Mail Stop Issue Fee
 Commissioner for Patents
 P.O. Box 1450
 Alexandria, VA 22313-1450

**AMENDMENT, PETITION AND FEE TO CORRECT INVENTORSHIP
 (37 C.F.R. § 1.48(a)) including PETITION UNDER 37 C.F.R. § 1.47(a)
 submitted AFTER ALLOWANCE (37 C.F.R. § 1.312)**

This amendment and petition is to correct the original naming of inventor(s) in an *original* declaration as set forth and filed on September 28, 2004. The application has been allowed and inventorship is now corrected consistent with the allowed claims. Conduct of two joint inventors, Justin L. Fort and Charles P. Fort, who signed the original declaration now constitutes a refusal to sign the *supplemental* declaration filed relative to this correction of inventorship.

ADDITION AND/OR DELETION OF INVENTOR(S)

- ☒ Add the following previously unnamed person(s) as inventor(s) of this application:

Mats Lagmanson, Liz Lagmanson, Markus Lagmanson and Bo Berglund.

- ☐ Delete the following previously incorrectly named inventor(s):

n/a.

Attached are:

- (a) a **Statement** (see Exhibit A) from:

- ☒ each person being added as an inventor that the error in inventorship occurred without deceptive intention on his or her part. 37 C.F.R. § 1.48(a)(1).
- ☐ each person being deleted as an inventor that the error in inventorship occurred without deceptive intention on his or her part. 37 C.F.R. § 1.48(a)(1).

- (b) a **supplemental Declaration** (see Exhibit B) by each of the actual inventor(s) as required by 37 C.F.R. § 1.63 (or as permitted by §§ 1.42, 1.43, or 1.47). 37 C.F.R. § 1.48(a)(2). As indicated above, two joint inventors, Justin L. Fort and Charles P. Fort, who signed the original declaration now refuse to sign the *supplemental* declaration filed herewith. Therefore, a petition under 37 C.F.R. § 1.47(a) including proof of pertinent facts accompanies this filing.
- (c) written **Assent of the Assignee** (see Exhibit C). 37 C.F.R. § 1.48(a)(4).

PETITION UNDER 37 C.F.R. § 1.47(a)

Attached hereto is a Declaration executed by all available joint inventors, i.e., *Mats Lagmanson, Liz Lagmanson, Markus Lagmanson and Bo Berglund*. The declaration is made on behalf of non-signing joint inventors, *Justin L. Fort and Charles P. Fort*, for whom respective signature blocks remain blank. See MPEP 409.03(a).

By conduct, summarized below in the Statement of Facts, *Justin L. Fort and Charles P. Fort*, now **refuse to sign** the attached Declaration.

Last Known Address of the Non-Signing Inventor(s)

Justin L. Fort
19501 Brue Street
Pflugerville, Texas 78660

Charles P. Fort
16721 Marsala Springs Drive
Round Rock, Texas 78621

Statement of Facts

On or about, February 22, 2008, Assignee of record, Advanced GeoSciences, Inc. (AGI) received an assignment of all right, title and interest in and to the present application from then named inventors, Justin L. Fort and Charles P. Fort. Both had previously been AGI employees and the assignment was one component of a settlement of litigation in which AGI asserted misappropriation. A copy of that assignment is recorded in the USPTO at reel 020551, frame 0934. Thereafter, the undersigned undertook prosecution of the present application and substantially amended claims.

Based on initial indications that certain of the claims would be allowable, the undersigned (after consultations with AGI personnel) determined that additional inventors should properly be named. Beginning in mid-June 2009, the undersigned initiated contacts with Justin L. Fort and Charles P. Fort, first via eMail and subsequently by certified mail regarding revised formal documents to add Mats Lagmanson, Liz Lagmanson, Markus Lagmanson and Bo Berglund as co-inventors. Specific correspondence with Justin L. Fort and Charles P. Fort is summarized as follows:

Date	Correspondence/Item	Attached As
June 16, 2009	eMail <i>to</i> Charles P. Fort (rockforts@austin.rr.com) and Justin L. Fort (justin4t@msn.com), transmitting a copy of allowable claim and requesting review in advance of formal papers.	Exhibit D
June 30, 2009	eMail <i>to</i> Charles P. Fort (rockforts@austin.rr.com) and Justin L. Fort (justin4t@msn.com), following up and indicating desired to discuss appropriate formal papers.	Exhibit E
July 5, 2009	eMail response <i>from</i> Charles P. Fort (rockforts@austin.rr.com).	Exhibit F
July 5, 2009	eMail reply <i>to</i> Charles P. Fort (rockforts@austin.rr.com) and Justin L. Fort (justin4t@msn.com), proposing specific dates (27/28 July 2009) for conference.	Exhibit G
July 27, 2009	eMail follow-up <i>to</i> Charles P. Fort (rockforts@austin.rr.com) and Justin L. Fort (justin4t@msn.com).	Exhibit H
August 13, 2009	eMail <i>to</i> Charles P. Fort (rockforts@austin.rr.com) and Justin L. Fort (justin4t@msn.com), advising that eMail was last informal communication and that formal correspondence would follow.	Exhibit I
September 17, 2009	Letter correspondence to Charles P. Fort at last known address (via certified mail, return receipt requested, item #70081140000226924222). Letter correspondence requested review of documents and return of signed declaration and included copy of application as filed, copy of amended claims, the declaration (for signature) and stamped, self-addressed return envelope.	Exhibit J
September 17, 2009	Letter correspondence to Justin L. Fort at last known address (via certified mail, return receipt requested, item #70081140000226924239). Letter correspondence requested review of documents and return of signed declaration and included copy of application as filed, copy of amended claims, the declaration (for signature) and stamped, self-addressed return envelope.	Exhibit K
September 18, 2009	Courtesy copy (by eMail <i>to</i> Charles P. Fort, rockforts@austin.rr.com) of September 17, 2009 letter correspondence including copies of application as filed,	Exhibit L

Date	Correspondence/Item	Attached As
	copy of amended claims and declaration (for signature).	
September 18, 2009	Courtesy copy (by eMail to Justin L. Fort, justin4t@msn.com) of September 17, 2009 letter correspondence including copies of application as filed, copy of amended claims and declaration (for signature).	Exhibit M
September 19, 2009	Delivery Confirmation for item #70081140000226924222 (addressed to Charles P. Fort) DELIVERED as confirmed by US Postal Service Track and Confirm	Exhibit N
September 22, 2009	Delivery Confirmation for item #70081140000226924239 (addressed to Justin L. Fort) DELIVERED as confirmed by US Postal Service Track and Confirm and return postcard.	Exhibit O

No response has been received to the undersigned's letter correspondence requesting review of documents and return of the signed declaration. No reason for such refusal has been given. Once (and only once on July 5, 2009), Charles P. Fort responded to eMail correspondence (directed to rockforts@austin.rr.com) indicating that Justin would be available to discuss after July 22, 2009 upon return from out-of-country travel. No further response has been received from either Charles P. Fort or Justin L. Fort. On information and belief, Justin L. Fort is Charles P. Fort's son.

CONCLUSION

As no response has been received to the undersigned's letter correspondence requesting review of documents and return of the signed declaration, the rule 47 applicant(s) conclude that conduct of Charles P. Fort and Justin L. Fort constitutes a **refusal to sign**.

FEE AUTHORIZATION

The Fees (under 37 C.F.R. §§ 1.48(a)(2), 1.17(i) and 1.17(g)) of \$330 are paid as follows:

- ☒ as directed in an electronic submission of this paper.
- ☐ by check enclosed herewith.
- ☐ Please charge the Fee shown above to Deposit Account 50-0631.
- ☒ The Commissioner is hereby authorized to charge any deficiency in fees and any additional fees under 37 C.F.R. § 1.16 or 1.17, that may be required during the pendency of this application, and to similarly credit any overpayment, to Deposit Account 50-0631

CERTIFICATE OF MAILING OR TRANSMISSION

I hereby certify that, on the date shown below, this correspondence is being

- ☐ deposited with the US Postal Service with sufficient postage as first class mail in an envelope addressed as shown above.
☐ facsimile transmitted to the USPTO.
☒ transmitted using the USPTO electronic filing system.

From: David W. O'Brien
Sent: Tuesday, June 16, 2009 7:20 PM
To: 'rockforts@austin.rr.com'; 'justin4t@msn.com'
Subject: US Patent Application 10/827,104 (our ref. 121-0003)
Attachments: 121-0003_Allowable_Claims.pdf

Gentlemen,

Each of you is presently-listed as an inventor in the above-identified patent application, which is now assigned to Advanced Geosciences, Inc. (AGI). As you may already know, we have amended claims during the course of prosecution in view of prior art cited by the USPTO and to achieve appropriate coverage. As a result, we are pleased to announce that the USPTO has indicated that a subset of claims are allowable.

The attached document shows those allowable claims.

We will soon proceed to grant. As a result, it is now appropriate to review the specifics of the claims and to revisit inventorship. After consulting with AGI personnel, it appears that (at least with respect to the allowable claims) Mats Lagmanson, Liz Lagmanson, Markus Lagmanson and Bo Berglund each have contributed to at least some aspect of at least one of the claims. Accordingly, we will need to list each them as an inventor.

Please take a moment to look over the allowed claims. I would like to briefly confer with you each to either (1) confirm that you (each individually) remain an inventor with respect to the actual claims that the USPTO is now willing to allow or (2) to discuss appropriate corrections. In either case, I'll have some formal documents for you to sign.

Basically, I need you each to tell me whether (or not) you contributed to any of the claims that are listed in the attached document. Please review the attached claims and respond with a phone number at which I can reach you. The phone call should take less than 5 minutes.

Thank you. I appreciate your time.

David

ALLOWABLE CLAIMS

3. A system for measuring a property at a surface, the system comprising:
a plurality of survey probes, each having a unique identifier; and
a survey controller configured to automatically poll the survey probes to obtain respective identifiers and determine a relative order of the probes,
each survey probe configured to:
disconnect a downstream neighbor survey probe and enter an idle state;
report its unique identifier to the survey controller if in the idle state and in response to a polling command from the survey controller; and
change to a state other than the idle state after reporting its unique identifier.
4. The system of claim 3, the survey controller configured to assign and transmit a different, unique identifier to each survey probe.
6. The system of claim 3, the survey controller and survey probes being connected by a first number of conductors, the survey probes being configured to perform a second number of simultaneous measurements of the surface, and the second number greater than, and not limited by, the first number.
7. The system of claim 3, the survey controller being remotely accessible through a computer network for remote control of the survey controller and the survey probes.
8. The system of claim 3, the survey probes being connected to the survey controller through three conductors, two conductors supplying power and a third conductor acting as a communications bus.
13. The system of claim 3,
wherein the survey controller is configured to individually program plural of the survey probes to inject current into the surface simultaneously or according to a programmed timing scheme.

15. The system of claim 3,

wherein the survey controller is configured to individually program respective ones of the survey probes to acquire geophysical data according to a programmed timing scheme.

47. A system for acquiring geophysical data based on measurements taken using survey probes, the system comprising:

a plurality of the survey probes, each having a unique identifier and each including data acquisition circuits and storage for measurements acquired thereby, the storage buffering the acquired measurements for subsequent, post-measurement transfer via a data communication interface; and

a survey controller communicatively coupled to receive from each of the survey probes its respective unique identifier, to automatically determine at least a relative ordering of the survey probes with respect to each other and to thereafter command individual ones of the survey probes based, at least in part, on the automatically determined relative ordering.

48. The system of claim 47,

wherein the survey probes are configured to isolate themselves from an external power supply connection, and to instead operate from an internal power source, for a period during which the respective survey probe collects geophysical data.

49. The system of claim 47,

wherein the relative ordering includes positional ordering, and

wherein each of the survey probes includes a radio frequency identification (RFID) transponder including memory for receiving positional information from a Global Positioning System (GPS) receiver proximate thereto, the survey probes configured to supply the survey controller with the received positional information in association with the respective unique identifier.

50. The system of claim 47, wherein the system determines relative ordering based on a startup sequence that includes:

each survey probe disconnecting its downstream neighbor and entering an idle state;
in response to a poll received from the survey controller while in the idle state, each
survey probe reporting its unique identifier; and
thereafter, a reporting one of the survey probes changing to a state other than the idle
state and reconnecting its downstream neighbor, if any, for subsequent polling by,
and reporting to, the survey controller.

51. A method for performing geophysical measurements, the method comprising:
obtaining a unique identifier from each of plurality of survey probes placed at a surface;
automatically determining a relative position of each of the survey probes as placed;
commanding individual ones of the survey probes using the obtained unique identifiers
and based on the determined relative positions thereof;
collecting geophysical data using the survey probes; and
storing the geophysical data in digital form at the respective survey probes for later
transmission to a survey controller.

52. The method of claim 51, wherein the survey probes are connected to the survey
controller by one or more conductors that supply power, the method further comprising:
automatically disconnecting individual ones of the survey probes from at least the power
supply conductors for a period that, for the respective survey probe, includes the
collecting of geophysical data; and
operating the survey probes when disconnected using an internal source of power to
reduce noise.

53. The method of claim 51, wherein the relative position is determined by the survey
controller based on a startup protocol that includes:

each survey probe disconnecting its downstream neighbor and entering an idle state;
in response to a poll received from the survey controller while in the idle state, each
survey probe reporting its unique identifier; and

thereafter, a reporting one of the survey probes changing to a state other than the idle state and reconnecting its downstream neighbor, if any, for subsequent polling by, and reporting to, the survey controller.

54. The method of claim 51, further comprising:

determining the relative positions of the survey probes using a radio frequency identification (RFID) transponder to uniquely identify each respective survey probe and a portable Global Positioning System (GPS) receiver to determine coordinates of a uniquely identified survey probe proximate thereto, associating coordinates determined by the GPS receiver with the identifying information for the proximate survey probe.

55. The method of claim 51, wherein the survey controller and survey probes are connected by a first number of conductors, the method further comprising:

performing a second number of simultaneous measurements with the survey probes, the second number greater than, and not limited by, the first number.

56. The method of claim 51, further comprising:

performing both seismic and electrical resistivity measurements using the same survey probes.

Subject: US Patent Application 10/827,104 (our ref. 121-0003)

Gentlemen,

Each of you is presently-listed as an inventor in the above-identified patent application, which is now assigned to Advanced Geosciences, Inc. (AGI). As you may already know, we have amended claims during the course of prosecution in view of prior art cited by the USPTO and to achieve appropriate coverage. As a result, we are pleased to announce that the USPTO has indicated that a subset of claims are allowable.

The attached document shows those allowable claims.

We will soon proceed to grant. As a result, it is now appropriate to review the specifics of the claims and to revisit inventorship. After consulting with AGI personnel, it appears that

(at least with respect to the allowable claims) Mats Lagmanson, Liz Lagmanson, Markus Lagmanson and Bo Berglund each have contributed to at least some aspect of at least one of the claims. Accordingly, we will need to list each them as an inventor.

Please take a moment to look over the allowed claims. I would like to briefly confer with you each to either (1) confirm that you (each individually) remain an inventor with respect to the actual claims that the USPTO is now willing to allow or (2) to discuss appropriate corrections. In either case, I'll have some formal documents for you to sign.

Basically, I need you each to tell me whether (or not) you contributed to any of the claims that are listed in the attached document. Please review the attached claims and respond with a phone number at which I can reach you. The phone call should take less than 5 minutes.

Thank you. I appreciate your time.

> Gentlemen,
>
> Each of you is presently-listed as an inventor in the above-identified
> patent application, which is now assigned to Advanced Geosciences,
> Inc. (AGI). As you may already know, we have amended claims during
> the course of prosecution in view of prior art cited by the USPTO and
> to achieve appropriate coverage. As a result, we are pleased to
> announce that the USPTO has indicated that a subset of claims are
> allowable.
>
> The attached document shows those allowable claims.
>
> We will soon proceed to grant. As a result, it is now appropriate to
> review the specifics of the claims and to revisit inventorship. After
> consulting with AGI personnel, it appears that (at least with respect
> to the allowable claims) Mats Lagmanson, Liz Lagmanson, Markus
> Lagmanson and Bo Berglund each have contributed to at least some
> aspect of at least one of the claims. Accordingly, we will need to
> list each them as an inventor.
>
> Please take a moment to look over the allowed claims. I would like to
> briefly confer with you each to either (1) confirm that you (each
> individually) remain an inventor with respect to the actual claims
> that the USPTO is now willing to allow or (2) to discuss appropriate
> corrections. In either case, I'll have some formal documents for you
> to sign.

>
> Basically, I need you each to tell me whether (or not) you contributed
> to any of the claims that are listed in the attached document. Please
> review the attached claims and respond with a phone number at which I
> can reach you. The phone call should take less than 5 minutes.
>
> Thank you. I appreciate your time.

RE: U.S. Patent Application entitled: "TECHNIQUES FOR SURFACE
EXPLORATION AND MONITORING"

Application No: 10/827,104

Our Reference: 121-0003

Dear Charles:

This formal written correspondence follows my prior electronic correspondence of 16 June 2009, 30 June 2009, 5 July 2009, 27 July 2009 and 13 August 2009 (to you at rockfortis@austin.rr.com and to your son Justin at justin4t@msn.com). Thank you for your response of 5 July 2009. Unfortunately, my subsequent correspondence remains unanswered. Accordingly, this formal written communication is being transmitted to you by certified mail to your postal address above.

ALLOWED CLAIMS

As you know, the above-identified pending US patent application names you and Justin Fort as inventors. On or about February 14, 2008, as part of a settlement of then ongoing litigation, both you and Justin assigned all right, title and interest in and to the above-identified application to your former employer, Advanced Geosciences, Inc. (AGI). Since then, my firm has, consistent with its representation of AGI, prosecuted the application to the point that the U.S. Patent Office (USPTO) has now identified certain claims that are allowable, i.e., which may mature into a granted US patent upon completion of certain formalities.

ADDITIONAL INVENTORS TO BE ADDED

In the course of our prosecution of the application, we have substantially amended the claims and it is these amended claims that the USPTO has indicated to be allowable. Based on our review, it appears that, at least with respect to the specific subject matter of claims as now amended, additional inventors contributed to the conception of the invention(s). Those additional inventors are: Mats Lagmanson, Liz Lagmanson, Markus Lagmanson and Bo Berglund.

Accordingly, consistent with USPTO regulations, we will petition to correct inventorship.

RE: 121-0003
Page 2 of 2

PREVIOUSLY NAMED INVENTORS

Because we have not been able to consult with you, I have been unable to ascertain whether, given the specific subject matter of claims as *now amended*, either you or Justin should continue to be named as inventors, or deleted. Depending on the nature of any contribution that you or Justin made to the claims as *now amended*, either answer may be correct. I remain available to discuss, should you be willing to do so.

Nonetheless, the time has come for us to proceed to grant. Accordingly, out of an abundance of caution, we have prepared appropriate formal papers consistent with the proposition that you and Justin have contributed in at least some inventive way to the claims as *now amended*.

For avoidance of doubt, I have included a copy of the application as filed, together with a copy of the claims as now amended. Please advise me immediately if you believe that, relative to the subject matter of the claims as now amended, either you or Justin should no longer be named as an inventor.

WHAT I NEED FROM YOU IS ...

Subject to the foregoing, and based on the assumption that both you and Justin should be named as inventors, attached is a Declaration for your signature. Please review, sign where indicated and return the executed copy to me in the stamped return envelope provided. I would appreciate your prompt reply.

Thank you for your attention. If you have any questions, please do not hesitate to contact me at the above-listed number.

Very truly yours,

David W. O'Brien

 - (2) Copy of Amended Claims
 - (3) Declaration (for signature)
 - (4) Stamped, Self-Addressed Return Envelope

DECLARATION

As a below-named inventor, I hereby declare that:

My residence, mailing address and citizenship are as stated below adjacent to my name.

I believe the below-named inventor or inventors are the original and first inventor or inventors of the subject matter that is claimed and for which a patent is sought by way of the application entitled

TECHNIQUES FOR SURFACE EXPLORATION AND MONITORING

which application bears the Attorney Docket Number stated above and which (if applicable or known):

☒ was filed on April 19, 2004 as Application No. 10/827,104 (if known)
☒ and was amended on March 12, 2009 (if applicable).

I have reviewed and understand the contents of the above-identified application, including the claims, as amended by any amendment specifically referred to above.

I acknowledge the duty to disclose to the U.S. Patent and Trademark Office all information known to me to be material to patentability as defined in Title 37, Code of Federal Regulations, § 1.56.

I declare that all statements made herein of my own knowledge are true, that all statements made on information and belief are believed to be true, and further that these statements were made with the knowledge that willful false statements and the like are punishable by fine or imprisonment, or both, under Title 18, United States Code, § 1001 and may jeopardize the validity of the application or any patent issuing thereon.

AMENDMENTS TO THE CLAIMS

Please amend the claims as indicated in the following listing of all claims:

1. (*Cancelled*)

2. (*Cancelled*)

3. (*Currently amended*) A system for measuring a property at a surface, the system comprising:

a plurality of survey probes, each having a unique identifier; and
a survey controller configured to automatically poll the survey probes to obtain respective identifiers and determine a relative order of the probes,
each survey probe configured to:
disconnect a downstream neighbor survey probe and enter an idle state;
report its unique identifier to the survey controller if in the idle state and in response to a polling command from the survey controller; and
change to a state other than the idle state after reporting its unique identifier.

4. (Previously presented) The system of claim 3, the survey controller configured to assign and transmit a different, unique identifier to each survey probe.

5. (*Cancelled*)

6. (Previously presented) The system of claim 3, the survey controller and survey probes being connected by a first number of conductors, the survey probes being configured to perform a second number of simultaneous measurements of the surface, and the second number greater than, and not limited by, the first number.

7. (Previously presented) The system of claim 3, the survey controller being remotely accessible through a computer network for remote control of the survey controller and the survey probes.

8. (Previously presented) The system of claim 3, the survey probes being connected to the survey controller through three conductors, two conductors supplying power and a third conductor acting as a communications bus.

9. *(Cancelled)*

10. *(Cancelled)*

11. *(Cancelled)*

12. *(Cancelled)*

13. (Previously presented) The system of claim 3,
wherein the survey controller is configured to individually program plural of the survey probes to inject current into the surface simultaneously or according to a programmed timing scheme.

14. *(Cancelled)*

15. (Previously presented) The system of claim 3,
wherein the survey controller is configured to individually program respective ones of the survey probes to acquire geophysical data according to a programmed timing scheme.

16. *(Cancelled)*

17. *(Cancelled)*

18. *(Cancelled)*

19. *(Cancelled)*

20. *(Cancelled)*

21. (Cancelled)

22. (Cancelled)

23. (Cancelled)

24. (Cancelled)

25. (Cancelled)

26. (Cancelled)

27. (Cancelled)

28. (Cancelled)

29. (Cancelled)

30. (Cancelled)

31. (Currently amended) A system for measuring a property [[of]] at a surface, the system comprising:

a plurality of survey probes; and

a ~~survey controller configured~~ power conduit coupled to supply power to the survey probes ~~using a power conduit~~;

wherein at least some of the survey probes automatically electrically disconnect from the power conduit while measuring the property and operate using an internal source of power when disconnected to reduce noise.

32. (Cancelled)

33. (Cancelled)

34. (Cancelled)

35. (Cancelled)

36. (Cancelled)

37. (Cancelled)

38. (Cancelled)

39. (Cancelled)

40. (Cancelled)

41. (Cancelled)

42. (Cancelled)

43. (Cancelled)

44. (Cancelled)

45. (Cancelled)

46. (Cancelled)

47. (Previously presented) A system for acquiring geophysical data based on measurements taken using survey probes, the system comprising:

a plurality of the survey probes, each having a unique identifier and each including data acquisition circuits and storage for measurements acquired thereby, the storage buffering the acquired measurements for subsequent, post-measurement transfer via a data communication interface; and

a survey controller communicatively coupled to receive from each of the survey probes its respective unique identifier, to automatically determine at least a relative ordering of the survey probes with respect to each other and to thereafter command individual ones of the survey probes based, at least in part, on the automatically determined relative ordering.

48. (Previously presented) The system of claim 47, wherein the survey probes are configured to isolate themselves from an external power supply connection, and to instead operate from an internal power source, for a period during which the respective survey probe collects geophysical data.

49. (Previously presented) The system of claim 47, wherein the relative ordering includes positional ordering, and wherein each of the survey probes includes a radio frequency identification (RFID) transponder including memory for receiving positional information from a Global Positioning System (GPS) receiver proximate thereto, the survey probes configured to supply the survey controller with the received positional information in association with the respective unique identifier.

50. (Previously presented) The system of claim 47, wherein the system determines relative ordering based on a startup sequence that includes:
each survey probe disconnecting its downstream neighbor and entering an idle state; in response to a poll received from the survey controller while in the idle state, each survey probe reporting its unique identifier; and
thereafter, a reporting one of the survey probes changing to a state other than the idle state and reconnecting its downstream neighbor, if any, for subsequent polling by, and reporting to, the survey controller.

51. (*Currently amended*) A method for performing geophysical measurements, the method comprising:
obtaining a unique identifier from each of plurality of survey probes placed at a surface;
automatically determining a relative position of each of the survey probes as placed;

commanding individual ones of the survey probes using the obtained unique identifiers and based on the determined relative positions thereof;
collecting geophysical data using the survey probes; and
storing the geophysical data in digital form at the respective survey probes for later transmission to a survey controller.

52. (Previously presented) The method of claim 51, wherein the survey probes are connected to the survey controller by one or more conductors that supply power, the method further comprising:

automatically disconnecting individual ones of the survey probes from at least the power supply conductors for a period that, for the respective survey probe, includes the collecting of geophysical data; and
operating the survey probes when disconnected using an internal source of power to reduce noise.

53. (Previously presented) The method of claim 51, wherein the relative position is determined by the survey controller based on a startup protocol that includes:

each survey probe disconnecting its downstream neighbor and entering an idle state; in response to a poll received from the survey controller while in the idle state, each survey probe reporting its unique identifier; and
thereafter, a reporting one of the survey probes changing to a state other than the idle state and reconnecting its downstream neighbor, if any, for subsequent polling by, and reporting to, the survey controller.

54. (Previously presented) The method of claim 51, further comprising:

determining the relative positions of the survey probes using a radio frequency identification (RFID) transponder to uniquely identify each respective survey probe and a portable Global Positioning System (GPS) receiver to determine coordinates of a uniquely identified survey probe proximate thereto, associating coordinates determined by the GPS receiver with the identifying information for the proximate survey probe.

55. (Previously presented) The method of claim 51, wherein the survey controller and survey probes are connected by a first number of conductors, the method further comprising: performing a second number of simultaneous measurements with the survey probes, the second number greater than, and not limited by, the first number.

56. (Previously presented) The method of claim 51, further comprising: performing both seismic and electrical resistivity measurements using the same survey probes.

57. (New) The method of claim 31, wherein the measured property includes either or both of electrical resistivity and induced polarization; and wherein, during the measuring, at least one particular one of probes remains electrically connected to the power conduit and receives current supplied thereby for injection at the surface.

58. (New) The method of claim 31, further comprising: a survey controller, wherein the power is supplied from the survey controller via the power conduit.

Application For United States Letters Patent

for

Techniques for Surface Exploration and Monitoring

by

Justin L. Fort

and

Charles P. Fort

CERTIFICATE OF EXPRESS MAIL

NUMBER EV 323284238 US

DATE OF DEPOSIT April 19, 2004

This application claims priority to, and incorporates by reference, U.S. provisional patent application Serial No. 60/463,499, which was filed on April 18, 2003.

BACKGROUND

This section provides the reader with a brief background of technology in the context of embodiments of this disclosure. Not only does this section provide context for several shortcomings in prior technology, but it also provides context about how the prior technology could, and will, benefit from various techniques described here. Simply because information appears in this section should not be taken as indicating its presence in the prior art. To the contrary, and as described immediately above, this section also provides context for certain significant improvements described and claimed in this disclosure.

Often specific survey objectives cannot be met by applying only one geophysical method. For example, in seismic and sonic reflection surveys, seismic refraction lines provide important information about velocities of near-surface materials which make it possible to apply needed corrections to reflection travel times. As electrical resistivity surveys depend on different physical properties than seismic or sonic surveys, the two taken together can provide important cross checks. If a system could perform multiple survey methods, better information about, for instance, the shallow subsurface could be obtained with a single multi-method survey.

Furthermore, there is developing interest in repeating surveys to observe changes that may occur in the subsurface, such as seasonal changes in groundwater level, effectiveness of subsurface pollutant remedial activities, and soil movement and water

penetration under roadways, bridges, and dams. This usually requires that equipment be in place for long periods of time and necessitates frequent visits to the survey sites by geophysical technicians to monitor changing subsurface conditions.

5 The present state of the art does not provide an effective way to remotely manage field equipment and monitor survey data, much less monitor data in real-time. Field personnel must travel to the sites, perform the survey, collect the data in a temporary data storage device, and carry the data to a data center for processing and analysis. This may be done monthly, weekly, or more frequently depending upon how quickly the subsurface feature being monitored changes.

10 During a survey, one may discover that equipment performance has degraded or some components are not performing at all. Presently, he or she must then contact a service technician by telephone to report the problem, resulting in lengthy and sometimes confusing attempts to diagnose the problem and repair the equipment. The result is that the service technician must travel to the site to diagnose the problem, or the equipment
15 must be sent to a service center for diagnosis and service.

20 Often, when equipment is returned to a service center, the equipment is found to be in satisfactory condition, and the problem remains at the site. This results in excessive "down-time" in the field and unplanned and excessive costs. If a means to remotely manage survey equipment and collect survey data were incorporated into a survey system, significant operational and cost advantages would accrue. For example, electrical resistivity strategies could be changed remotely and interactively from Dipole-Dipole to Wenner/Leed by the investigator. Measurement parameters such as injection

current magnitude and period, survey frequency and method could be changed. Remote tests and diagnostics could be performed on all equipment to determine their level of operability and specific equipment requiring service.

5 A further disadvantage of present survey systems, in particular systems for the electrical resistivity, is the lengthy time required to perform a typical survey. Time limitations are due primarily to internal instrument noise caused by conductive coupling between cable conductors and connector pins (signal to noise ratio). The number of receivers active during a survey event is currently limited by the number of conductors in a cable. If a system were to eliminate the coupling noise and to remove the limitations
10 on the number of receivers, shorter survey times could be achieved—from hours to minutes for a typical 100-survey probe system. This could result in survey crew labor savings and overall greater productivity.

Present electrical resistivity survey systems require multi-conductor cabling to simultaneously carry high voltage and low level analog potential signals. Multiple cable
15 segments with integrated survey probes are connected together in the field in preparation for surveys. The cable segments must be connected with very careful attention to the order in which they are connected. Whether passive survey probes or intelligent survey probes, incorrect connections result in unintelligible and useless data. If an electrical resistivity survey system did not require cables to simultaneously carry high voltage and
20 low voltage signals, data accuracy would be improved. Cables could be lighter and easier to handle in the field. Furthermore, if it were not required that cable sections must be connected in specific order, connection errors, survey errors, and field set-up time could

multi-method shallow subsurface exploration system capable of performing synchronized analog to digital conversion of AC and DC electrical signals detected at 2 to 1000 or more points in a probe survey array. The signal conditioning and A/D conversion can be performed locally at an intelligent survey probe which contains electrical components
5 such as a microprocessor, signal conditioning circuitry, short term energy storage, switching devices, and connections to one or more sensors and transducers associated with different exploration survey.

Embodiments of the invention provide a wireless link or, optionally, a conductor cable bus link for two-way communication between one or more survey controllers and
10 survey probes. Each means (wireless or conductor cable bus) may be most suitable for a particular embodiment and may depend on the type of survey to be performed. Each means requires the spatial location of stimulus and measurement probes.

In cable bus embodiments, a time-multiplexed conductor cable system can be used for two-way communication between a survey controller and each of multiple
15 survey probes, rather than by wireless means. The conductor cable system can provide for delivery of power from the survey controller to the survey probes.

In one embodiment, each survey probe is assigned a 4-byte serial number or other identifier. In one embodiment, such an identifier can be assigned at the time of manufacture. In cable bus embodiments, the serial number or other identifier can be
20 obtained as the survey probe is connected to the cable in the field prior to survey events, or at any time after connection to the cable bus. This eliminates the requirement to connect survey probes in a specific order. Accordingly, a survey probe can be accessed

by a command message from the survey controller using either the survey probe's serial number or a field-assigned access number or other identifier. A serialized access number is one convenient way to access survey probes from the survey controller, although it will be recognized that other techniques could be used.

5 Assignment of access numbers can follow a startup protocol. When a survey probe is first connected to a survey controller cable, it can receive power, initialize and send a data message to the communication data bus announcing its serial number or identifier. The survey controller can respond by sending a message to the survey probe serial number or identifier found in the incoming message, assigning an access number to
10 the survey probe. The survey probe can accept the access number, acknowledge execution of the command, and enter an idle or standby state. This process can continue for each survey probe. In one embodiment, this process can continue until the operator signifies to the survey controller that the last survey probe has signed in or until the signing-in of the last probe is detected automatically.

15 In another startup protocol, one or more survey probes are connected on a survey controller cable and the cable is terminated on a survey controller. The survey controller applies power to the cable causing each survey probe to execute a start up protocol, disconnect its down-stream neighbor from the signal bus, and enter an idle state. Downstream refers to survey probes toward the end of the cable and away from the
20 survey controller. The survey controller transmits a special broadcast command to the cable to command any survey probe in idle state to report its serial number code. Only the first survey probe receives the command (all the other down-stream neighbors are

disconnected) and responds with its survey probe serial number code. The survey controller receives the serial number code from the first survey probe and can respond with a command to the first survey probe to accept a different identifier as its access code. The first survey probe can change its access code to this different identifier, exit
5 from the idle state and proceed to state S1. The first survey probe can reply to the survey controller confirming its access code and connects the second downstream survey probe to the cable. At this point in the process, the only survey probe in the idle state is the second survey probe. The cycle continues until no further responses are received from the special broadcast command, which result in the reporting of serial number codes. In
10 this manner, each probe is automatically identified, associated with a unique identifier, and its order relative to the other probes (first probe, second probe, third probe, etc.) is determined. As will be recognized by those having ordinary skill in the art, this process can save a significant amount of time because the survey controller can now automatically determine probe order and identifiers during, for instance, a startup
15 protocol.

In one embodiment, the investigator, prior to starting the survey, manually records the positions of all connected survey probes according to their respective identifier. The survey controller knows the access identifier and the order of each survey probe in the cable network and is prepared to execute surveys.

20 In a different embodiment, the position of each survey probes is determined wirelessly by measuring its distance from two or more reference point locations generally positioned on the survey site.

In a wireless embodiment, one can determine the spatial location of each survey probe using radio, sonic or optical position transceivers. Each survey probe measures its distance from one or more position-transmitter sources, one of which may be the survey controller. These measurements are transmitted to the survey controller. From these
5 measurements, the survey probe calculates its distance from each position transmitter source and reports this information and its identifier to the survey controller. The survey controller can use this information to control the survey. The survey controller can assign a unique access number or other identifier to each survey probe.

Another embodiment of a wireless technique for determining spatial position of a
10 survey probe uses an RFID transponder, such as Texas Instruments RI-TRP-B9WK, associated with each survey probe. The transponder is responsive to interrogation by an RFID reader such as the portable TI Series 2000 reader system. A differential GPS receiver is also used, and this receiver can be integrated with the RFID reader. The RFID reader can be placed near a probe for interrogation. The reader interrogates the RFID
15 transponder and receives the transmitted data. The data, unique to each transponder, is received and combined with the reported Differential GPS longitude, altitude, and latitude measured at the probe. This data can be stored in the RFID memory until communicated to the survey controller.

In a wireless embodiment for determining spatial position using the known
20 position transmitter positions, the survey controller can also calculate relative positions of survey probes and convert them to standard longitude, latitude, and elevation coordinates, or another convenient coordinate system, for each survey probe. Generally, two properly

positioned position transmitters are required for survey probe location in a two dimensional space, and three are required for locating survey probes within a three dimensional space.

5 In wireless embodiments, each survey probe thereafter may be accessed by either its serial number or access number in subsequent message packets or by way of other wireless transmission techniques known in the art.

10 In different embodiments, probes can be connected to survey controllers by cable for transmission of operating power, stimulus (power to energize stimulus transducers, such as current injection) as required by the survey controller's survey program, and for signal measurement reference. Two conductors can carry power to the survey probes for charging one or more temporary energy storage devices, the electronics, and relays during a survey dwell time. These two conductors can also carry high energy to power stimulus injectors during a survey event and complete the circuit to a high energy power supply. It is to be noted that passive survey events can be performed by measuring
15 natural induced potentials without the injection of a stimulus into the earth. The third conductor can provide a reference for potential measurements during the survey event, and, in conjunction with one of the power conductors, a data communication bus (e.g., a bus between survey events).

20 According to different embodiments, electrical resistivity measurements can be made by applying a voltage to cause a measured current flow between two or more stimulus points on a surface such as the earth's surface (e.g., stimulus points). Differences of the induced voltage potentials between one or more measurement points

can be determined. The potential measurement data and current flow data and probe positions can be processed by the application of known mathematical processes, typically reduced to computer programs. Using the mathematical processes, the resistivity of a subsurface can be deduced or inferred.

5 In reference to 3-conductor embodiments described above, the third conductor can provide for a common potential to which all or a number of survey probes measure induced potentials. The third conductor can be electrically-connected to some point in the earth or on the current injection source. Since survey probe measurements can be made relative to this common potential, the potential difference between participating
10 survey probes can then be calculated, and the resistivity determined as just previously described.

 The third conductor can also provide for measurement of the potential difference only between two adjacent survey probe points. Survey probes can measure potentials relative to that of a specified neighboring survey probe. Segments of the third conductor
15 can be switchable to provide the connections between the survey probes, operating to provide a reference voltage during the survey event. This reference can also be switchable to provide a common reference voltage to all survey probes.

 Different embodiments also provide the ability to measure the potential change of a measurement point due to an injection stimulus. The measurement point can be
20 measured prior to a current injection. This same point can be again measured after the injection stimulus. The difference is taken. This difference is the potential change due to the injection stimulus. The survey controller can signal each survey probe a

predetermined time prior to stimulus injection. At this time after a programmed delay, each survey probe can sample and hold the data collected. In different embodiments, each probe can delay for a pre-programmed delay time after a signal has been received from the survey controller, before the probe begins to sample. In one embodiment, the default delay time is zero. However, each probe may be setup by the survey controller with a different delay-to-sample.

In reference to 3-conductor embodiments described above, the third conductor can carry data (*e.g.*, via data packets or other known means) to and from survey probes and a survey controller during, *e.g.*, the survey dwell time that is between survey events. For example, data packets may contain commands from the survey controller which are decoded by the accessed survey probe to set-up or prepare for a survey event, or it may be a command to the accessed survey probe to transmit survey data from a previous survey event.

During a survey event, the third conductor can be switched to a reference voltage, such as earth ground by the survey controller. Reference ground can be used by each survey probe as a reference signal for sensor signal measurements. Simultaneously or at a different time, the survey probe can disconnect itself from the two power conductors and obtain operating power from its energy storage device. In one embodiment, the energy storage device can be a 0.1 Farad capacitor manufactured by AVX Corp., part number BZ015A104ZHB, or equivalent. The value of the capacitor may differ for different embodiments. This capacitor can be charged during the dwell time and contains sufficient energy to operate the survey probe during the survey time. One advantage of

using a capacitor is that it does not need replacement as do batteries, it eliminates the maintenance due to battery replacement, it eliminates the need for battery charging circuitry, and it eliminates environmental issues associated with disposing of large numbers of batteries. Use of an internal energy source such as a capacitor beneficially
5 allows for the isolation of the survey probe from the survey controller during the survey event and significantly reduces noise. Another embodiment isolates all survey probes completely, connecting only to an adjacent survey probe and recording the difference potential measured between the two survey probes.

In conventional systems, dc power is generated and delivered to all probes
10 directly from a central power source and is usually regulated at individual probes. This dc power line, even though filtered at each probe, typically picks up radiated noise from the environment due to long cable runs. Each probe therefore contributes filtered noise to the conducted digital noise to the dc power distribution conductors to all other probes. Any ripple or transient noise induced by the central power supply contributes noise.
15 Although conventional practice involves filtering the dc power line with high pass filter capacitive networks, the filtered noise is applied to the ground circuit of each probe. This noise finds its way into the measurements of all other probes.

Another source of noise can be high voltage injection current conductor, which is, in interest of economy, usually carried in the same cable with (a) the dc power conductor,
20 (b) the dc power ground, (c) the high voltage return conductor, (d) the signal conductors and (e) the signal return conductor common to all signal conductors. Also there can be large current and high voltage transients during any injection period, which can couple

noise to the micro-volt level signals on signal conductors, significantly decreasing the signal to noise ratio of the measurement and requiring complex filtering processes and circuitry to minimize the deleterious effects. This occurs during the period that the very sensitive measurements are being made.

- 5 Embodiments of this disclosure virtually eliminate external noise problems by having all (or a subset of) probes isolate themselves from these external noise sources during a measurement period. Furthermore, digital data representing the measurements can be transmitted during a dwell time and are virtually insensitive to noise on the cable.

- 10 In embodiments of the disclosure, signals can be conditioned and digitized directly from conductive stakes or other transducers such as motion, sound, magnetic, or gravimetric transducers properly coupled to *e.g.*, the earth surface or boreholes through the surface.

- 15 Prior to a survey event, each survey probe can receive a setup command data packet from a survey controller specifying its function during the survey event as mentioned above. Any survey probe can be adapted to function by command as a signal receiver and processor, or stimulus injector. For example, in the case of the electrical resistivity method configuration, a survey probe can be adapted to function as an electrical current injector.

- 20 In one embodiment, survey probes receive a first synchronizing signal from a survey controller and each probe proceeds to configure itself according to the setup command it received from the survey controller by operating switches and initializing a correct program to perform the tasks and selecting the signal source for the A/D converter

in preparation for the survey event.

In this embodiment, survey probes receive a second synchronizing signal and those survey probes assigned the task of stimulus or scheduled injection proceed to inject the stimulus into the surface, which in one embodiment may be according to a pre-
5 programmed time delay and period. All survey probes assigned the task of receiver can delay for a programmed time period and commence to digitize and filter the signals received from the connected sensors, according to prescribed processing algorithms. Survey probes can accumulate processed signal data until requested by the survey controller. In one embodiment, simultaneous to receiving the second synchronizing
10 signal, survey probes assigned the function of stimulator injector can direct high power voltage through their switches to their corresponding connected stimulators. The stimulator might be a magnetic hammer for sound or seismic method, or a metal stake for current injection for electrical resistivity method. Other stimulators known in the art can also be used.

15 At the conclusion of a survey event, each survey probe can enter an idle mode and reconnect power and one or more communication conductors to the energy storage device and communications device, respectively, in preparation for receiving a message from a survey controller to report its results of the survey. A survey controller program then can optionally command each survey probe to report the data it captured during the survey
20 event. If no such command is received by a survey probe, it can store the results for future delivery at the request of the survey controller. If another survey event is to occur, the survey controller can send new setup information to each survey probe in preparation

for the next survey event, and the cycle can be repeated.

In one embodiment, access to the survey controller is provided by a local or remote Internet browser or by way of another computer network. A web server can be embedded within a survey controller, and the server can include software to interact with survey probes. A local or remote browser can effect secure download of applications programs and diagnostic software to specific survey probes. The survey controller can accept uploads from the remote browser to initiate built-in test software, to report key system operational data, to collect survey data, update information and survey instructions, and/or other functions with which the survey controller software has access to.

In one embodiment, communication server function is provided in one or more survey controllers in the survey environment, and the one or more controllers are connected to a remote network. Connection to the remote network may be by satellite or terrestrial means. In one embodiment, primary communication can be accomplished between survey controllers and any communicating device accessible via the Internet by using techniques known in the art of communications such as techniques the Hypertext transfer protocol(HTTP) and hypertext markup language(HTML), and/or (XML) Extended Markup Language. Each survey controller can be adapted to facilitate real-time access between a survey controller and a remote device upon access of a particular page, script, or function.

In one embodiment, executable content is embedded in one or more HTML pages so that when a page is loaded onto an HTML browser after being accessed, the

executable content starts running automatically. The executable content can act to perform specified data transfer operations between the browser and one or more survey controllers. Additionally, survey controllers' operating systems, upon detection of an urgent local event, can request or initiate a session with an appropriate, predetermined remote terminal device or server for service.

In one respect, the invention involves a system for measuring a property of a surface, the system including a plurality of survey probes and a survey controller. Each of the of the survey probes has a unique identifier, and the survey controller is configured to automatically poll the survey probes to obtain each identifier and determine a relative order the probes. In one embodiment, polling can occur once during a startup protocol, although it will be understood that it could occur at different times/frequencies throughout any given process. In one embodiment, the polling may take place as follows: each survey probe can be configured to (a) disconnect a downstream neighbor survey probe and enter an idle state; (b) report its unique identifier to the survey controller if in the idle state and in response to a polling command from the survey controller; and (c) change to a state other than the idle state after reporting its unique identifier. In other embodiments, different steps may be taken that are suitable to convey unique identifiers to the survey controller and to convey relative ordering of the probes. This, of course, greatly improves the state of the art in which determination of probe ordering is typically handled manually in a time consuming manner. The survey controller can be configured to assign and transmit a different, unique identifier to each survey probe. The survey controller and survey probes can be configured to communicate wirelessly. The survey

controller and survey probes being can be connected by a first number of conductors, the survey probes can be configured to perform a second number of simultaneous measurements of the surface, and the second number need not be limited by the first number. Accordingly, the system can be set up to do a number of simultaneous
5 measurements independent of the number of conductors connecting probes to the survey controller. For instance, although probes may be connected, in one embodiment, to the survey controller using three conductors, far more than three simultaneous measurements can be performed. The survey controller can be remotely accessible through a computer network for remote control of the survey controller and the survey probes. In one
10 embodiment, this computer network is the Internet, although other networks can be utilized as well. The survey probes can be connected to the survey controller through three conductors, two conductors supplying power and a third conductor acting as a communications bus.

In another respect, the invention involves a system for measuring a property of a
15 surface, the system including a survey controller and a plurality of survey probes that are configured to: (a) collect signals associated with the surface; (b) digitize the signals to form digital data; and (c) store the digital data for later transmission to the survey controller. The survey probes can be configured for performing both electrical and seismic measurements, and the signals can include seismic or electrical signals. The
20 signals associated with the surface can include signals that are generated in response to the surface being stimulated. For example, the signals can be in response to electrical and/or seismic stimulation. In other embodiments, the signals can result from a passive

state of the surface. The survey controller and survey probes can be configured to communicate wirelessly. The survey controller can send data to individually program survey probes to generate a stimulus simultaneously or according to another programmed timing scheme. The stimulus can include injection of current. The survey controller can send data to individually program survey probes to form digital data and store the digital data according to a programmed timing scheme. The survey controller and survey probes being can be connected by a first number of conductors, the survey probes can be configured to perform a second number of simultaneous measurements of the surface, and the second number need not be limited by the first number. Such an embodiment and its advantages are described immediately above. The survey controller can be remotely accessible through a computer network (e.g., the Internet) for remote control of the survey controller and the survey probes. The survey probes can be connected to the survey controller through three conductors, two conductors supplying power and a third conductor acting as a communications bus.

In another respect, the invention involves a system for measuring a property of a surface, the system including a survey controller and a plurality of survey probes that are configured to: (a) collect signals associated with the surface; and (b) sample and hold the signals for later transmission to the survey controller.

In another respect, the invention involves a system for measuring a property of a surface, the system comprising a survey controller and a plurality of individually-addressable survey probes, where the survey controller is configured to: (a) transmit a first signal to individually program survey probes to conduct one or more steps for

measuring the property of the surface and (b) transmit a second signal to cause survey probes to conduct the one or more steps according to a timing sequence. Accordingly, the survey controller can send programming instructions to individual probes and then send instructions to carry out the program. Such instructions can be sent remotely over a computer network such as the Internet. Such embodiments provide for a level of flexibility and convenience not known in the art. The survey controller and survey probes can be configured to communicate wirelessly. The survey controller can further be configured to transmit a third signal to diagnose survey probes. This, among other things, eliminates or reduces the need for on-site technicians to perform diagnostics on probes. The survey controller and survey probes can be connected by a first number of conductors, the survey probes can be configured to perform a second number of simultaneous measurements of the ground, and the second number need not be limited by the first number. As mentioned above, the survey controller can be remotely accessible through a computer network for remote control of the survey controller and the survey probes. The survey probes can be connected to the survey controller through three conductors, two conductors supplying power and a third conductor acting as a communications bus.

In another respect, the invention involves a system for measuring a property of a surface, the system including a survey controller and a plurality of individually-addressable survey probes, where the survey controller is configured to transmit a diagnostic signal to individual survey probes to diagnose the individual survey probes.

In another respect, the invention involves a system for measuring a property of a

surface, the system including a survey controller and a plurality of survey probes whose position relative to one another is automatically determined. This advantageously allows for much more efficient measurement techniques because the system can itself determine physical relative and/or absolute locations of probes. In one embodiment, a transmitting
5 beacon is provided, and the position is determined using a signal from the transmitting beacon. In another embodiment, a radio frequency identification (RFID) system is coupled to the probes and a Global Positioning System (GPS) is used. The position is determined by combining identification information from the RFID system with positional location from the GPS. In another embodiment, the RFID system can alone be
10 used to identify individual probes and report that information, including information about the relative ordering of the probes, to the survey controller. The survey probes can be in motion. In such an embodiment, even if the probes are being, e.g., pulled behind a boat, their relative positions can be continuously determined. This offers great advantages over the current state of the art.

15 In another respect, the invention involves a system for measuring a property of a surface, the system including a plurality of survey probes and a survey controller configured to supply power to the survey probes using a power conduit. The survey probes automatically electrically disconnect from the power conduit while measuring the property and operate using an internal source of power when disconnected to reduce
20 noise. This reduction of noise offers great advantages over the current state of the art such as improved accuracy of measurements.

In another respect, the invention involves a system for measuring a property of a

surface, the system including a plurality of survey probes and a survey controller configured to program the same survey probes for seismic or electrical measurements of the surface. Accordingly, one system of survey probes and controller(s) can be used not only to do electrical resistivity measurements, but can also be used to perform seismic
5 measurements. Currently, two separate systems would be necessary. Those having ordinary skill in the art with the benefit of this disclosure will recognize that even additional different types of measurements can be performed with a single system. Allowing such flexibility is, among other things described here, the ability to individually program survey probes to follow instructions dictated by the survey controller (e.g., to
10 follow instructions to produce a certain type of stimulus and/or to receive data according to specified timing schemes). Each other embodiment of this disclosure can also exhibit this significant advantage, allowing for different types of properties of a surface to be measured with different measurement techniques (e.g., but not limited to, electrical and/or seismic) using a single measurement system that is configured to be programmed
15 for different types of measurements according to different timing schemes and the like.

In another respect, the invention involves system for measuring a property of a surface, the system including a plurality of survey probes and a survey controller that is remotely accessible through a computer network for remote control of the survey probes, the remote control including: (a) remote initiation of a measurement of the property of
20 the surface and (b) remote collection of data from a measurement of the property of the surface. In one embodiment, the network can be the Internet. The remote control can further include remote processing of data from a measurement of the property of the

surface. The remote control can further include remote diagnostic testing of survey probes. The computer network can include a wireless network.

5 In another respect, the invention involves a system for measuring a property of a surface, the system including a plurality of survey probes and a survey controller configured to program the plurality of survey probes to simultaneously apply a stimulus to the surface in an arbitrary pattern. In conventional systems running electrical measurements, point source injection of current is the norm. Using techniques of this disclosure, however, one is not limited to such point injection. Rather, one can simultaneously inject current using several different probes in an arbitrary pattern to create, e.g., a line-source injection, a traveling pattern, etc. In one embodiment, the pattern includes a line pattern, and in another embodiment, the pattern includes a moving wave pattern. Many other patterns and schemes can be used as will be recognized by those of ordinary skill in the art to perform several measurements that, until now, have been effectively impossible.

15 In another respect, the invention involves a method for measuring a property of a surface, the method including: collecting signals associated with the surface using a plurality of survey probes; digitizing the signals using the plurality of survey probes to form digital data; and storing the digital data using the plurality of survey probes for later transmission to a survey controller. The method can also include: polling the survey probes using the survey controller to automatically: (a) obtain an identifier of each survey probe; and (b) determine a relative order of the survey probes. The survey controller and survey probes can be connected by a first number of conductors, and the

method can also include performing a second number of simultaneous measurements with the survey probes, the second number not being limited by the first number. The method can also include: controlling data acquisition, data processing, or data collection associated with the survey controller remotely over a computer network. The survey probes can be connected to the survey controller by one or more conductors that supply power, and the method can also include automatically disconnecting the survey probes from the one or more conductors while measuring the property and operating using an internal source of power when disconnected to reduce noise. The method can also include automatically determining the relative position of the survey probes. The relative position can be determined using (a) a transmitting beacon or (b) a radio frequency identification (RFID) system and a Global Positioning System (GPS). The method can also include performing a seismic and electrical measurement of the surface using the same survey probes.

In the embodiments described here, the term “surface” is broad and encompasses any surface or sub-surface. A surface can include surfaces of water, ground, underwater surfaces, man-made surfaces, borehole surfaces, borehole subsurfaces, etc. As used herein, “automatically” distinguishes an act done manually by, for instance, a technician. In preferred embodiments, “automatic” tasks are done via computer instructions that dictate certain tasks be done by one or more computers or computer-operated hardware. As used in the claims, the indefinite articles “a” and “an” mean one or more unless explicitly noted otherwise. For instance, although claims may state “a” survey controller, it will be understood that the claim encompasses and contemplates situations in which

more than one controller is used. The term "comprising" in the claims is an open-ended term. "Couple" means a direct or indirect connection.

Other advantages and features of embodiments of this disclosure will be apparent with reference to the following drawings and the additional description that follows.

5 **BRIEF DESCRIPTION OF THE DRAWINGS**

 The drawings accompanying and forming part of this specification are included to depict certain aspects of the invention. A clearer conception of the invention, and of the components and operation of systems provided with the invention, will become more readily apparent by referring to the exemplary, and therefore nonlimiting, embodiments
10 illustrated in the drawings, wherein like reference numerals (if they occur in more than one view) designate the same or similar elements. The invention may be better understood by reference to one or more of these drawings in combination with the description presented here. It should be noted that the features illustrated in the drawings are not necessarily drawn to scale.

15 FIG. 1 is a drawing depicting a wide area network of multiple survey controllers connected through the Internet or locally according to embodiments of this disclosure.

 FIG.2 is a drawing illustrating an example sequence for a client browser to establish a session with an embedded web server survey controller according to embodiment of this disclosure.

20 FIG. 3 is a block diagram of an example exploration survey system having an array of survey probes connected by cable to a survey controller according to embodiments of the present disclosure.

FIG. 4 is a block diagram of a survey probe according to embodiments of the present disclosure.

FIG. 5 is a plan drawing depicting a cable interconnected array of survey probes arrayed and connected to a survey controller according to embodiments of the present disclosure.

FIG. 6 is a horizontal section through the earth showing vertically arranged survey probes in a borehole interconnected by cable segments according to embodiments of the present disclosure.

FIG. 7 is a horizontal section view of a linear array of survey probe mounted on conductive stakes inter-connected by cable segments according to embodiments of the present disclosure.

FIG. 8 is a view of an embodiment of a survey probe with cables and connectors according to embodiments of the present disclosure attached to a conductive stake in the ground.

FIG. 9 is a drawing depicting multiplexing of power to survey probes according to embodiments of the present disclosure.

FIG. 10 depicts a system synchronizing signal derived at each survey probe according to embodiments of the present disclosure.

FIG. 11 depicts operating timing of system relays according to embodiments of the present disclosure.

FIG. 12 is a schematic of a Survey Controller Program in accordance with embodiments of the present disclosure.

DETAILED DESCRIPTION OF EXAMPLE EMBODIMENTS

Referring now to the drawings it will be understood that the illustrations and accompanying text are provided to describe example embodiments and are not intended to limit the invention herein. It is the claims that define the invention.

5 Certain aspects of this disclosure focus on the electrical resistivity survey method managed by a local or remote browser. It will be clear to those having ordinary skill in the art that the following description applies equally well to other survey method applications known in the art. Neither this disclosure nor the claims (unless explicitly stated otherwise) are limited to a particular type of survey method such as electrical
10 resistivity.

 The World Wide Web is a collection of servers of the Internet that use the hypertext transfer protocol (HTTP). HTTP is a known application protocol that provides users with access to files, which can be in different formats, such as text, graphics, images, sound and video using a standard page description language, HTML. HTML
15 provides basis document formatting and allows the developer to specify links to other servers and files therein. Use of an HTML compliant client browser involves specification of a link having a URL. Upon such specification, the client makes a request to the server identified in the link and receives a web page, basically in document format, according to HTML, in return. HTML provides exceptional freedom in creating
20 graphics/text/graphic images and associated audio between servers and client browsers. HTTP and HTML allow complex services to be accessed by clients having a minimum amount of hardware sophistication.

Turning now to FIG. 12, a typical survey controller program 77 (*see*, FIG. 3) for a survey controller 1 embedded microprocessor 21 is shown. The survey controller program includes a network connection 108 having multiple hardware and/or software ports or addresses, 32, 34, 110. The survey controller program has a controller and software tasks including survey manager 118, survey probe manager 115, power source control 116, cable multiplex control 117, system diagnostic manager 120, software download manager 119, associated with RAM/flash memory cooperating to run under operating system 87C, server or server task 112 in cooperation with the network connection 108 which provides access to the survey controller 1 server from a local Client Terminal browser 5 (*see*, FIG. 1) or remote Client Terminal browser 7 (*see*, FIG. 1) on a local network or the internet. The local browsers 5 are typically able to access the server task 112 of the survey controller 1. Preferably, the browsers 7 may also access the server 112 of survey controller directly. A software task is defined very broadly to include both separate and integrated software embodiments which may or may not run concurrently with other software.

An embedded function 87B can be integrated with a page 87A. The page 87B may be a basic HTML page, script, function or like program. The embedded function may be attached to a header of the page 87A or otherwise associated with the page wherein one of two events occurs when the page is accessed. First, the page 87A along with the embedded function 87B can be delivered to the browser that accessed the server and page. Alternatively, the embedded function 87A can be adapted to run on the server from which the page was accessed, even though the page is delivered to the appropriate

browser. In the first case, the embedded function can be adapted to run at the browser. In the second case, the embedded function can run at the server that the browser accessed.

In one embodiment, the embedded function is any executable content, such as
5 Java applets. The executable content may be one or more small applications that conform to a restricted set of programming standards for running on browsers. When the embedded function is sent to the browser upon accessing a page, the function can be run at the browser to facilitate connection back to a specific server and server location. In another embodiment, the embedded function can run at the server and act to keep the
10 existing connection open as well as to periodically send updated HTML pages. This latter technique places fewer demands on a browser's application capabilities but is less flexible. The remote browser or client may store data and determine how often to update or to request an update. The parameters relating to periodic updates may be stored locally at the remote browser, or may be downloaded to the survey controller. In the
15 latter case the server task 112 may take the responsibility of periodically sending data to the remote browser without a request from the remote browser.

In one embodiment, a user at the browser 5 or 7 starts a browser application and connects to a homepage at a site's uniform resource locator (URL) address. An example process, where embedded functions are actually transferred to the browser from the
20 accessed server, is outlined in FIG. 2. It will be understood that FIG. 2 serves to illustrate several other embodiments as well. In one such embodiment, communications are provided between the survey controller 1 at the survey site and a browser 5 or 7,

preferably running on a client PC. For example, the browser may be located at a remote site on the Internet or other similar network in addition to being located at the survey site.

Initially, a user at the browser 5 or 7 can start a browser application and connect to a homepage at a site's uniform resource locator (URL) address (block 101). An HTTP
5 server 1 having the URL address at the survey controller can deliver a home page for a site asset management system to the browser 7 (block 102). The user at browser 5 or 7 can select a defined link on the homepage to access and monitor a select function in the survey controller (block 103). In one example, the selected function can be the survey controller's completed survey result file (block 106). The server can generate a status
10 page containing executable content, *e.g.* a Java Applet, and deliver the page and the executable content to the client (block 105). For ease of understanding, this executable content can generally be referred to as the embedded function.

The client's browser 5 or 7, can load the page from the survey controller 1 and run the embedded function (executable content), which can immediately connect back to
15 the selected service device, preferably using a separate address and protocol (block 105). The device will accept the connection initiated by the embedded function and begin delivering status data (in one embodiment, in real time) to the client browser 5 or 7.

In addition to monitoring selected information at various ports and addresses at the selected device server, the connection between the browser and the selected device
20 may provide for any type of uploading or downloading of information, software, or control data to monitor, access, and otherwise reconfigure any portion of the survey site addressable and accessible through the server.

For example, the client browser 5 or 7 may download a new configuration or software upgrade for survey probes, survey controller, or any other programmable device or data source addressable and accessible through the server. Additionally, the browser may simply gather completed survey files or in-process survey data.

5 Figure 3, another example embodiment, includes a survey controller 1 connected by cables 11 including, in a preferred embodiment, not more than 3 conductors, to an array of autonomous survey probes 12. In other embodiments, more or fewer than 3 conductors can be used, as will be recognized by those having ordinary skill in the art with the benefit of this disclosure.

10 In the example embodiment of FIG. 3, a survey event is created when an electrical current is forced through the earth between two or more survey probe 12 electrodes 50, and when two or more different survey probes 12 sense, digitize, and store the induced potentials detected by their respective electrodes 50. PS 22 and associated circuitry provide the electrical current. The timing and value of said electrical current is
15 prescribed by Survey Control Program (SCP) 77. The survey event is completed when each different survey probes 12 report the digitized potential measurements to Survey Controller 1, or when Survey Controller Program proscribes that survey probes store the measurements for later reporting.

 Referring now to FIG. 9, the horizontal axis indicates the time sequence of
20 voltage transitions on conductor 45. The transitions are fixed in sequence but vary in time as operably prescribed by CMC 117, and are labeled T^0 , T^1 , T^2 , and T^3 . State S0 begins with time T^0 and ends with T^1 , state S1 begins at time T^1 and ends at time T^2 ,

state S2 begins at time T^2 and ends with time T^3 , state S3 begins at T^3 and ends at time T^0 . The vertical axis represents the magnitude of voltage measurable on cable conductor 45 relative to cable 46.

Now also referring to FIG. 3, during state S0, CMC 117 operates to de-activate relay coil 18A, connecting communication transceiver 27 to cable 11, conductor 47 through relay 18B contact pair B-A. SPP 78 of all survey probes 12, cooperatively deactivate relay coils 90, thereby connecting transceivers 54 to conductor 47 through relays 90A contacts A-B, providing a communication link between SPP 78 and SPM 115. SPM 115 and SPP 78 cooperatively operate to exchange messages, to setup for the next survey event, to report measurement data, and other messages necessary for coordination between survey controller 1 and survey probes 12.

At the beginning of state S1, PSC 116 operates to apply power to all survey probes 12 through conductors 45 and 46. Next, SPM 118 operates to initialize each participating survey probe 12 in preparation for collecting survey data from each "sensor" survey probe 12 and preparing for the next survey event.

PS 26 is a programmable power supply provided with conductor 61 for current return through relay 18DE, conductor 109 connecting to power gate 25 and to communication transceiver 27. Data bus 37 is provided for exchange of digital command and data between PSC 116 and PS 26. PS 26 is adaptable to receive commands from PSC 116, and operates to adjust output voltage to values prescribed by PSC 116 and to report actual output voltage values to PSC 116. Signal line 36 is provided for CMC 117 to signal Power Gate 25. CMC 117 is operable to signal Power Gate 25 to permit said

current flow during state S1 and to block current flow during states S0, S2, and S3. Power Gate 25 is adaptable to respond to signals from control line 36 to block or permit current flow from PS 26 to meter 23. Data bus 34 is provided exchange of digital information between PSC 116 and programmable meter 23. Conductor 88 is provided to
5 connect the output of Gate 24 and Gate 25 to meter 23. Meter 23 is adaptable to sensing, measuring, and digitizing the electrical current magnitude flowing from conductor 88 to conductor 45 and responsive to PSC 116 to report said digitized value to data bus 34 upon command by PSC 116. During S1, meter 23 signals PSC 116 that current flow has reached a prescribed value indicating that C1 energy storage devices are charged and that
10 survey probes 12 are prepared to receive setup assignments for the next survey event to occur during the following state S3. SPM 118 then operates to send set-up command messages to each survey probe 12 prescribing each survey probe's function to be performed during the survey event.

For the purpose of better understanding the present invention, the following
15 scenario is presented as a simplified example of the processes which take place during state S1. SPM 115 commands each survey probe 12 to perform specific functions for the duration of the survey event. The functions are current injection, current receiver, and ground voltage potential sensor. For example, survey probe 12 "A" is assigned to current injection function, survey probe 12 "B" is assigned current receiver function to receive
20 injection current, completing the path to PS 22 through the earth during the survey event. Survey probes 12 "C", "D", "E", "-Z". are assigned ground voltage potential sensors to sense, digitize, and record voltage potentials appearing at their respective electrodes 50 or

48, and are hereafter known as sensors.

Using signal line 36, CMC 117 signals gate 25 to close. Closure of gate 25 is detected by circuit 38 which signals SPP 78 over conductor 52. SPP 78 detects that the system is in state S2. SPP 78 of each survey probe proceeds to perform their respective
5 setup instructions received from CMC 117.

Paths through relay contacts are specified by the numerical relay actuator number following by the contact pair completing a circuit. For example, 18BA refers to the contacts B and A of relay actuator 18.

SPP 78 operates relay actuator 18, to establish a return path from cable conductor
10 46 through 18DF, conductor 55, to PS 22 return 55. Operation of relay actuator 18 also establishes a connection from cable conductor 47, connector 79, 18AC, conductor 40, to reference ground.

To continue the example, survey probe 12 "A" is assigned injection function. The associated SPP 78 operates relay actuators 89, 91, 90, and 92 through port
15 connections to microprocessor 69, establishing a current path from cable conductor 47, through relay contacts 89AC, 91AC, conductor 85, contacts 92AC, connector 74 to electrode 50. Survey probe 12, and SPP 78 become idle until state S3 is detected by circuit 38, signaling SPP 78 through conductor 52. "A" survey probe 12 is thereby prepared as current injector.

20 Survey probe 12, "B" is assigned current return function. The associated SPP 78 operates relays actuator 89, 90, 92 through port connections to microprocessor 69. These relays establish a return current path from electrode 50, through connector 74, through

relay contacts 92AC, conductor 85, relay contacts 91AB, 89FD, connector 70, cable conductor 46, connector 79, relay contacts 18DF, conductor 55, to PS 22 return 55. Survey probe 12, and SPP 78 become idle until state S3 is detected by circuit 38 and signaled to SPP 78 through conductor 52. "B" survey probe 12 is thereby prepared as
5 current receiver.

Survey probes 12 "C", "D", "E" -"Z" are assigned "sensor" function. The associated SPP 78 operates relay 89, and 90 to establish a circuit from electrode 50, connector 74, contacts 92AB, conductor 80, through signal conditioner 64, to signal line 49 to input multiplexor 65 of microprocessor system 51. SPP 78 operates to provide
10 common reference to multiplexor 65 from conductor 40, through contacts 18CA, conductor 41 connector 79, cable conductor 47, connector 70, through relay contact 90AC, to conductor 107. "Sensor survey probes" 12, SPP 78 becomes idle until state S3 is detected by circuit 38 and signaled to SPP 78 through conductor 52. "Sensor" survey probes 12 are thereby prepared as current receiver

15 To begin the survey event, PSC 116 operates to program injector PS 22 to the prescribed voltage during state S2 and adjusts PS 22 voltage to limit current through meter 23 during the survey event to the prescribed value.

At the beginning of state S3, CMC 117 operates to open power gate 24 which applies the output of injection PS 22 to electrode 50 of "A" survey probe 12, producing a
20 current flow from electrode 50 through the earth to "B" survey probe 12, producing potentials at the surface measured and digitized by "sensor" survey probes 12.

Circuits 38 at each survey probe 12 operate to detect the transition from state S2

to state S3, corresponding to T^3 , synchronizing the ADCs of all "sensor" survey probes

12. All "sensor" survey probes' SPP 78 operate to produce the prescribed number of ADC samples of the arithmetical difference between reference signal 44 and electrode 50 sensor signals, performs the prescribed filtering processes, and other prescribed data processing of the sensed voltage potentials during state S3, and stores the results in RAM/FLASH memory 62.

CMC 117 operates to enter state S0 by closing power gate 24. Circuits 38 of each survey probe detect removal of injection voltage from cable conductor 45 and signal the change to state S0 to SPP 78s via conductor 52. All survey probes SPP 78 operate to deactivate all relay actuators 89, 90, 91, and 92 and enter state S1.

Referring to FIGS. 1, 2, 4, diagnostic testing and calibration of the multiplexor 65 and ADC 66 can be initiated by the a Client Terminal Browser by the investigator if accuracy of the data is questioned or programmatically by Survey Controller program 77 upon occurrence of a particular event detectable by SCP 77. In other embodiments, diagnostic testing can be initiated for any other reason. In one embodiment, SCP 77 issues a command SPP 69 to execute a certain calibration and functional test of the multiplexor 65 and ADC 66. In one embodiment, ADC 66 operates to apply a precision internally sourced test voltage internally through multiplexor 65, internal buffer amplifier, and to ADC 66. A measurement of the precision voltage is taken and compared to the known, expected value. SPP 78 adjusts gain and offset values of the internal buffer amplifier to achieve the expected value. Survey Probe Program 78 calibrates ADC 66. The Survey Controller may operate to send a command to SPP 78 to

execute a measurement of, for instance, a 9 volt un-regulated voltage by commanding the multiplexor 65 to apply the voltage on conductor 57 to the ADC 66 and instruct ADC 66 to measure, digitize, and store the value in memory. If the voltage is found to be less than the stipulated value at the time specified, an abnormal event can be recorded and transmitted to the SCP 77, which places the measurement in an abnormal event file in RAM/Flash memory 29 for analysis by a remote operator. An authorized operator may access Survey Controller Program's 77's webpage and through the processes identified in Fig. 2, access the abnormal event File. Other diagnostic tests appropriate for the particular embodiment are similarly implemented.

Referring to FIGS. 3 and 4, electronic switching device, 71 is connected through relay contact 89CA operable to modulate the electrical current passing through the circuit comprising PS 22, Gate 24, conductor 88, current meter 23, connector 79, to cable conductor 45 through relay contact 89AC, to conductor 56, to input to switching device 71, output from switching device 71, through relay contacts 91CA, conductor 85 through relay contacts 92CA, to connector 74, to one electromechanical, magnetic, or electrical stimulus injectors to receive electrical stimulation from connector 74, in response to signals applied to conductor 63 by SPP 78.

For electrical stimulus injectors, such as used in the electrical resistivity method embodiment of the present invention, the stimulus is an electrical current passing from the current injection survey probe 12, metal stake 50, through the earth, to the receiver metal stake 50 of receive survey probe 12, through relay contacts 92AC, conductor 85, through relay contacts 91AB, through relay contacts 89FD, through connector 70, cable

conductor 46, through conductor 40, through relay contacts 18DF, to conductor 55, to injector PS 22 return.

For electromechanical, magnetic, radio frequency, or other electrical stimulus injector embodiments of the present invention, the stimulus apparatus receives power through PS22, power gate 24, conductor 88, CM 23, connector 79, conductor 45, connector 70, relay contacts 89AC, current sensor 71A, current modulator 71, relay contacts 91CA, conductor 113, relay contacts 92CA, connector 74 and 74A, with return path through relay contacts 89FD, connector 70, to cable conductor 46, through connector 79, through relay contacts 18DF, through conductor 55, and to PS 22 return.

Electrical, vibration, seismic, magnetic, and other sensors connect to signal conditioner 64, through differential connectors 75B and 75C, conductors 83 and 84, through signal conditioner 64, to multiplexor 65 adaptable to apply the difference signal to analog to digital converter 66. SPP 78 operates to perform digital signal processing and filtering of the digitized data operates to store said data into RAM/Flash Memory, accessible to survey controller Survey probe Manager (SPM) 29 on command. Microphone 85 connects through conductor 72 to multiplexor 65. Also referring to FIG.8, Microphone 85 is coupled to the survey probe housing 49 coupled to conductive stake 50, adapted to produce electrical signals corresponding to sensed vibrations conducted from the ground 76, through conductive stake 59. Said signals are applied to multiplexor 65 through conductor 72. SPP 78 is operative to apply said signals through multiplexor 65 to ADC 66 for digitizing and filtering, and storing the digitized signals in RAM/Flash memory 62 available for access by SCP 77.

Referring to FIGS. 3, 4 and 5, a linear survey measurement cable array 11a is assembled on site by connecting a first cable 11 from survey controller 1 to a first survey probe 12, a second cable 11, from the first survey probe to a second survey probe, and a next cable 11 from the second survey probe to a next survey probe, until all the survey probes have been connected as shown in array 19. Connection of a survey probe 12 onto the chain, operates to charge energy storage device C1 of said survey probe. Power from C1 is supplied to operate said survey probe electronics 12. SPP 78 operates to initialize all electronics to state S1 and to send a data message to SCP 77 to announce its addition to the cable array. Said data message contains the serial number assigned during manufacture. SCP 77 responds to said data message with a command message containing a new address field. SPP 78, receives said command message, extract said new address field and stores it in memory 62. SPP 77 will generally operate to send future command messages to said survey probe addressing it by the new address.

A second embodiment of the present invention operates to acquire the survey probe serial number and operates to address future commands to said survey probe addressing it by said serial number. SPM 115 operates to maintain survey probe serial numbers, together with the order in which said serial number is reported, in RAM/FLASH memory 62. Said reporting order is the ordinate location on the array cable.

Referring FIG. 4, Temp Sensor 67 is adapted to sense the internal temperature of embedded computer 51 and produce a signal corresponding to the temperature. Periodically or on command by SCP 77, SPP 78 operates to measure the temperature and

with an internally generated precise reference voltage, perform a calibration process and make compensations and adjustments to said components to assure accurate operation of the multiplexor, internal buffers, amplifiers, and other internal circuits during survey events. SPP 78 operates to measure +9vdc 57 voltage level of energy source C1 at
5 prescribed times and calculates the operating time remaining before SPP 78 places embedded system 51 in idle mode to reduce power consumption.

Referring to FIG.8, conductive stake 50 is inserted into the earth operating to make electrical contact with the earth and to mount spring steel stake connector 74. Spring steel stake connector 74 fastens to conductive stake 50 and operates to mount
10 survey probe 12 onto stake 50 and provide electrical contact between contact rings 131 and conductive stake 50. Survey probe 12 comprises housing 124, assembled printed circuit board 112, PVC end plate 125 operating to seal the PCB assembly 112 from ingress of water and other chemicals and vapors. Female connector tubes 134 penetrate
15 PVC end plate 125 and PVChousing 124 and are sealed at holes of ingress 127, 126, 128, and 129 of housing 124 and at corresponding holes through end plate 125. Connector tubes 134 are soldered to PCB 112 solder pads and solder rings 121 which operate to conduct signals and power to PCB 112. Contact pins 132 operate to make electrical
20 contact between contact rings 131 and Relay 92 contact A of FIG.4. Connector 70 comprises molded connector shell 133, spring loaded bayonet type connector pins 130 electrically attached to conductors of cable segment 11, and low density compressible filler 135. Connectors 70 operate to make electrical contact between conductors of cable 11 and corresponding female connector tubes 134 when joined to survey probe housing

124. Low density compressible filler 135 operates to protect connectors pins 130 when not mated to housing 124.

Claims:

1. A system for measuring a property of a surface, the system comprising:
 - a plurality of survey probes; and
 - a survey controller configured to program the same survey probes for seismic or electrical measurements of the surface.
2. A system for measuring a property of a surface, the system comprising:
 - a plurality of survey probes, each having a unique identifier; and
 - a survey controller configured to automatically poll the survey probes to obtain each identifier and determine a relative order the probes.
3. The system of claim 2, each survey probe configured to:
 - disconnect a downstream neighbor survey probe and enter an idle state;
 - report its unique identifier to the survey controller if in the idle state and in response to a polling command from the survey controller; and
 - change to a state other than the idle state after reporting its unique identifier.
4. The system of claim 2, the survey controller configured to assign and transmit a different, unique identifier to each survey probe.
5. The system of claim 2, the survey controller and survey probes configured to communicate wirelessly.
6. The system of claim 2, the survey controller and survey probes being connected by a first number of conductors, the survey probes being configured to perform a second number of simultaneous measurements of the surface, and the second number not being limited by the first number.

7. The system of claim 2, the survey controller being remotely accessible through a computer network for remote control of the survey controller and the survey probes.
8. The system of claim 2, the survey probes being connected to the survey controller through three conductors, two conductors supplying power and a third conductor acting as a communications bus.
9. A system for measuring a property of a surface, the system comprising:
a survey controller; and
a plurality of survey probes configured to:
(a) collect signals associated with the surface;
(b) digitize the signals to form digital data; and
(c) store the digital data for later transmission to the survey controller.
10. The system of claim 9, where the survey probes are configured for performing both electrical and seismic measurements, and the signals comprising seismic or electrical signals.
11. The system of claim 9, the signals associated with the surface comprising signals that are generated in response to the surface being stimulated.
12. The system of claim 9, the survey controller and survey probes configured to communicate wirelessly.
13. The system of claim 9, the survey controller sending data to individually program survey probes to generate a stimulus simultaneously or according to another programmed timing scheme.
14. The system of claim 13, the stimulus comprising injection of current.

15. The system of claim 9, the survey controller sending data to individually program survey probes to form digital data and store the digital data according to a programmed timing scheme.
16. The system of claim 9., the survey controller and survey probes being connected by a first number of conductors, the survey probes being configured to perform a second number of simultaneous measurements of the surface, and the second number not being limited by the first number.
17. The system of claim 9, the survey controller being remotely accessible through a computer network for remote control of the survey controller and the survey probes.
18. The system of claim 9, the survey probes being connected to the survey controller through three conductors, two conductors supplying power and a third conductor acting as a communications bus.
19. A system for measuring a property of a surface, the system comprising:
a survey controller; and
a plurality of survey probes configured to:
 (a) collect signals associated with the surface; and
 (b) sample and hold the signals for later transmission to the survey controller.
20. A system for measuring a property of a surface, the system comprising:
a survey controller; and
a plurality of individually-addressable survey probes;
where the survey controller is configured to:
 (a) transmit a first signal to individually program survey probes to conduct one or more steps for measuring the property of the surface; and

- (b) transmit a second signal to cause survey probes to conduct the one or more steps according to a timing sequence.

21. The system of claim 20, the survey controller and survey probes configured to communicate wirelessly.

22. The system of claim 20, the survey controller further configured to transmit a third signal to diagnose survey probes.

23. The system of claim 20., the survey controller and survey probes being connected by a first number of conductors, the survey probes being configured to perform a second number of simultaneous measurements of the ground, and the second number not being limited by the first number.

24. The system of claim 20, the survey controller being remotely accessible through a computer network for remote control of the survey controller and the survey probes.

25. The system of claim 20, the survey probes being connected to the survey controller through three conductors, two conductors supplying power and a third conductor acting as a communications bus.

26. A system for measuring a property of a surface, the system comprising:
a survey controller; and
a plurality of individually-addressable survey probes;
where the survey controller is configured to transmit a diagnostic signal to
individual survey probes to diagnose the individual survey probes.

27. A system for measuring a property of a surface, the system comprising:
a survey controller; and
a plurality of survey probes whose position relative to one another is automatically determined.
28. The system of claim 27, further comprising a transmitting beacon and where the position is determined using a signal from the transmitting beacon.
29. The system of claim 27, further comprising a radio frequency identification (RFID) system coupled to the probes and a Global Positioning System (GPS), the position being determined by combining identification information from the RFID system with positional location from the GPS.
30. The system of claim 27, the survey probes being in motion.
31. A system for measuring a property of a surface, the system comprising:
a plurality of survey probes; and
a survey controller configured to supply power to the survey probes using a power conduit;
where the survey probes automatically electrically disconnect from the power conduit while measuring the property and operate using an internal source of power when disconnected to reduce noise.
32. A system for measuring a property of a surface, the system comprising:
a plurality of survey probes; and
a survey controller that is remotely accessible through a computer network for remote control of the survey probes, the remote control comprising:
(a) remote initiation of a measurement of the property of the surface; and

- (b) remote collection of data from a measurement of the property of the surface.

33. The system of claim 32, the remote control further comprising remote processing of data from a measurement of the property of the surface.

34. The system of claim 32, the remote control further comprising remote diagnostic testing of survey probes.

35. The system of claim 32, the computer network comprising a wireless network.

36. A system for measuring a property of a surface, the system comprising:
a plurality of survey probes; and
a survey controller configured to program the plurality of survey probes to simultaneously apply a stimulus to the surface in an arbitrary pattern.

37. The system of claim 36, the pattern comprising a line pattern.

38. The system of claim 36, the pattern comprising a moving wave pattern.

39. A method for measuring a property of a surface, the method comprising:
collecting signals associated with the surface using a plurality of survey probes;
digitizing the signals using the plurality of survey probes to form digital data; and
storing the digital data using the plurality of survey probes for later transmission to a survey controller.

40. The method of claim 39, the method further comprising:
polling the survey probes using the survey controller to automatically:
(a) obtain an identifier of each survey probe; and
(b) determine a relative order of the survey probes.

41. The method of claim 39, where the survey controller and survey probes are connected by a first number of conductors, and the method further comprising performing a second number of simultaneous measurements with the survey probes, the second number not being limited by the first number.

42. The method of claim 39, the method further comprising:

controlling data acquisition, data processing, or data collection associated with the survey controller remotely over a computer network.

43. The method of claim 39, the survey probes being connected to the survey controller by one or more conductors that supply power, and the method further comprising automatically disconnecting the survey probes from the one or more conductors while measuring the property and operating using an internal source of power when disconnected to reduce noise.

44. The method of claim 39, the method further comprising automatically determining the relative position of the survey probes.

45. The method of claim 44, where the relative position is determined using (a) a transmitting beacon or (b) a radio frequency identification (RFID) system and a Global Positioning System (GPS).

46. The method of claim 39, the method further comprising performing a seismic and electrical measurement of the surface using the same survey probes.

ABSTRACT

Techniques for surface exploration and monitoring are presented. In representative embodiments, a system is provided that can perform multiple types of measurements of a surface. For example a single system of survey probes and one or more survey controllers can be used to offer both seismic and electrical measurements. A survey controller can be configured to automatically poll survey probes to obtain identifiers of the probes and determine a relative order the probes. Survey probes can be configured to: (a) collect signals associated with a surface; (b) digitize the signals to form digital data; and (c) store the digital data for later transmission to the survey controller. Relative positions of survey probes can be automatically determined using a transmitting beacon or other techniques. Survey probes can automatically disconnect from a power conduit while measuring a surface property and operate using an internal source of power when disconnected, to reduce noise. The survey controller can be remotely accessible through a computer network for remote control of the survey probes.

RE: U.S. Patent Application entitled: "TECHNIQUES FOR SURFACE
EXPLORATION AND MONITORING"
Application No: 10/827,104
Our Reference: 121-0003

Dear Justin:

This formal written correspondence follows my prior electronic correspondence of 16 June 2009, 30 June 2009, 5 July 2009, 27 July 2009 and 13 August 2009 (to you at justin4t@msn.com and to your father at rockforts@austin.rr.com). Although your father responded 5 July 2009, I have not received a response from you and, in any case, my subsequent correspondence remains unanswered. Accordingly, this formal written communication is being transmitted to you by certified mail to your postal address above.

ALLOWED CLAIMS

As you know, the above-identified pending US patent application names you and Charles Fort as inventors. On or about February 14, 2008, as part of a settlement of then ongoing litigation, both you and Charles assigned all right, title and interest in and to the above-identified application to your former employer, Advanced Geosciences, Inc. (AGI). Since then, my firm has, consistent with its representation of AGI, prosecuted the application to the point that the U.S. Patent Office (USPTO) has now identified certain claims that are allowable, i.e., which may mature into a granted US patent upon completion of certain formalities.

ADDITIONAL INVENTORS TO BE ADDED

In the course of our prosecution of the application, we have substantially amended the claims and it is these amended claims that the USPTO has indicated to be allowable. Based on our review, it appears that, at least with respect to the specific subject matter of claims as now amended, additional inventors contributed to the conception of the invention(s). Those additional inventors are: Mats Lagmanson, Liz Lagmanson, Markus Lagmanson and Bo Berglund.

Accordingly, consistent with USPTO regulations, we will petition to correct inventorship.

Justin L. Fort

PREVIOUSLY NAMED INVENTORS

Because we have not been able to consult with you, I have been unable to ascertain whether, given the specific subject matter of claims as *now amended*, either you or Charles should continue to be named as inventors, or deleted. Depending on the nature of any contribution that you or Charles made to the claims as *now amended*, either answer may be correct. I remain available to discuss, should you be willing to do so.

Nonetheless, the time has come for us to proceed to grant. Accordingly, out of an abundance of caution, we have prepared appropriate formal papers consistent with the proposition that you and Charles have contributed in at least some inventive way to the claims as *now amended*.

For avoidance of doubt, I have included a copy of the application as filed, together with a copy of the claims as now amended. Please advise me immediately if you believe that, relative to the subject matter of the claims as now amended, either you or Charles should no longer be named as an inventor.

WHAT I NEED FROM YOU IS ...

Subject to the foregoing, and based on the assumption that both you and Charles should be named as inventors, attached is a Declaration for your signature. Please review, sign where indicated and return the executed copy to me in the stamped return envelope provided. I would appreciate your prompt reply.

Thank you for your attention. If you have any questions, please do not hesitate to contact me at the above-listed number.

Very truly yours,

David W. O'Brien

DECLARATION

As a below-named inventor, I hereby declare that:

My residence, mailing address and citizenship are as stated below adjacent to my name.

I believe the below-named inventor or inventors are the original and first inventor or inventors of the subject matter that is claimed and for which a patent is sought by way of the application entitled

TECHNIQUES FOR SURFACE EXPLORATION AND MONITORING

which application bears the Attorney Docket Number stated above and which (if applicable or known):

- ☒ was filed on April 19, 2004 as Application No. 10/827,104 (if known)
☒ and was amended on March 12, 2009 (if applicable).

I have reviewed and understand the contents of the above-identified application, including the claims, as amended by any amendment specifically referred to above.

I acknowledge the duty to disclose to the U.S. Patent and Trademark Office all information known to me to be material to patentability as defined in Title 37, Code of Federal Regulations, § 1.56.

I declare that all statements made herein of my own knowledge are true, that all statements made on information and belief are believed to be true, and further that these statements were made with the knowledge that willful false statements and the like are punishable by fine or imprisonment, or both, under Title 18, United States Code, § 1001 and may jeopardize the validity of the application or any patent issuing thereon.

AMENDMENTS TO THE CLAIMS

Please amend the claims as indicated in the following listing of all claims:

1. *(Cancelled)*

2. *(Cancelled)*

3. *(Currently amended)* A system for measuring a property at a surface, the system comprising:

a plurality of survey probes, each having a unique identifier; and
a survey controller configured to automatically poll the survey probes to obtain respective identifiers and determine a relative order of the probes,

each survey probe configured to:

disconnect a downstream neighbor survey probe and enter an idle state;
report its unique identifier to the survey controller if in the idle state and in response to a polling command from the survey controller; and
change to a state other than the idle state after reporting its unique identifier.

4. *(Previously presented)* The system of claim 3, the survey controller configured to assign and transmit a different, unique identifier to each survey probe.

5. *(Cancelled)*

6. *(Previously presented)* The system of claim 3, the survey controller and survey probes being connected by a first number of conductors, the survey probes being configured to perform a second number of simultaneous measurements of the surface, and the second number greater than, and not limited by, the first number.

7. *(Previously presented)* The system of claim 3, the survey controller being remotely accessible through a computer network for remote control of the survey controller and the survey probes.

8. (Previously presented) The system of claim 3, the survey probes being connected to the survey controller through three conductors, two conductors supplying power and a third conductor acting as a communications bus.

9. *(Cancelled)*

10. *(Cancelled)*

11. *(Cancelled)*

12. *(Cancelled)*

13. (Previously presented) The system of claim 3,
wherein the survey controller is configured to individually program plural of the survey probes to inject current into the surface simultaneously or according to a programmed timing scheme.

14. *(Cancelled)*

15. (Previously presented) The system of claim 3,
wherein the survey controller is configured to individually program respective ones of the survey probes to acquire geophysical data according to a programmed timing scheme.

16. *(Cancelled)*

17. *(Cancelled)*

18. *(Cancelled)*

19. *(Cancelled)*

20. *(Cancelled)*

21. (Cancelled)

22. (Cancelled)

23. (Cancelled)

24. (Cancelled)

25. (Cancelled)

26. (Cancelled)

27. (Cancelled)

28. (Cancelled)

29. (Cancelled)

47. (Previously presented) A system for acquiring geophysical data based on measurements taken using survey probes, the system comprising:
a plurality of the survey probes, each having a unique identifier and each including data acquisition circuits and storage for measurements acquired thereby, the storage buffering the acquired measurements for subsequent, post-measurement transfer via a data communication interface; and

a survey controller communicatively coupled to receive from each of the survey probes its respective unique identifier, to automatically determine at least a relative ordering of the survey probes with respect to each other and to thereafter command individual ones of the survey probes based, at least in part, on the automatically determined relative ordering.

48. (Previously presented) The system of claim 47, wherein the survey probes are configured to isolate themselves from an external power supply connection, and to instead operate from an internal power source, for a period during which the respective survey probe collects geophysical data.

49. (Previously presented) The system of claim 47, wherein the relative ordering includes positional ordering, and wherein each of the survey probes includes a radio frequency identification (RFID) transponder including memory for receiving positional information from a Global Positioning System (GPS) receiver proximate thereto, the survey probes configured to supply the survey controller with the received positional information in association with the respective unique identifier.

50. (Previously presented) The system of claim 47, wherein the system determines relative ordering based on a startup sequence that includes:
each survey probe disconnecting its downstream neighbor and entering an idle state; in response to a poll received from the survey controller while in the idle state, each survey probe reporting its unique identifier; and
thereafter, a reporting one of the survey probes changing to a state other than the idle state and reconnecting its downstream neighbor, if any, for subsequent polling by, and reporting to, the survey controller.

51. (**Currently amended**) A method for performing geophysical measurements, the method comprising:
obtaining a unique identifier from each of plurality of survey probes placed at a surface;
automatically determining a relative position of each of the survey probes as placed;

commanding individual ones of the survey probes using the obtained unique identifiers and based on the determined relative positions thereof;
collecting geophysical data using the survey probes; and
storing the geophysical data in digital form at the respective survey probes for later transmission to a survey controller.

52. (Previously presented) The method of claim 51, wherein the survey probes are connected to the survey controller by one or more conductors that supply power, the method further comprising:

automatically disconnecting individual ones of the survey probes from at least the power supply conductors for a period that, for the respective survey probe, includes the collecting of geophysical data; and
operating the survey probes when disconnected using an internal source of power to reduce noise.

53. (Previously presented) The method of claim 51, wherein the relative position is determined by the survey controller based on a startup protocol that includes:

each survey probe disconnecting its downstream neighbor and entering an idle state; in response to a poll received from the survey controller while in the idle state, each survey probe reporting its unique identifier; and
thereafter, a reporting one of the survey probes changing to a state other than the idle state and reconnecting its downstream neighbor, if any, for subsequent polling by, and reporting to, the survey controller.

54. (Previously presented) The method of claim 51, further comprising:

determining the relative positions of the survey probes using a radio frequency identification (RFID) transponder to uniquely identify each respective survey probe and a portable Global Positioning System (GPS) receiver to determine coordinates of a uniquely identified survey probe proximate thereto, associating coordinates determined by the GPS receiver with the identifying information for the proximate survey probe.

55. (Previously presented) The method of claim 51, wherein the survey controller and survey probes are connected by a first number of conductors, the method further comprising: performing a second number of simultaneous measurements with the survey probes, the second number greater than, and not limited by, the first number.

56. (Previously presented) The method of claim 51, further comprising: performing both seismic and electrical resistivity measurements using the same survey probes.

57. (New) The method of claim 31, wherein the measured property includes either or both of electrical resistivity and induced polarization; and wherein, during the measuring, at least one particular one of probes remains electrically connected to the power conduit and receives current supplied thereby for injection at the surface.

58. (New) The method of claim 31, further comprising: a survey controller, wherein the power is supplied from the survey controller via the power conduit.

Application For United States Letters Patent

for

Techniques for Surface Exploration and Monitoring

by

Justin L. Fort

and

Charles P. Fort

CERTIFICATE OF EXPRESS MAIL

NUMBER EV 323284238 US

DATE OF DEPOSIT April 19, 2004

This application claims priority to, and incorporates by reference, U.S. provisional patent application Serial No. 60/463,499, which was filed on April 18, 2003.

BACKGROUND

This section provides the reader with a brief background of technology in the context of embodiments of this disclosure. Not only does this section provide context for several shortcomings in prior technology, but it also provides context about how the prior technology could, and will, benefit from various techniques described here. Simply because information appears in this section should not be taken as indicating its presence in the prior art. To the contrary, and as described immediately above, this section also provides context for certain significant improvements described and claimed in this disclosure.

Often specific survey objectives cannot be met by applying only one geophysical method. For example, in seismic and sonic reflection surveys, seismic refraction lines provide important information about velocities of near-surface materials which make it possible to apply needed corrections to reflection travel times. As electrical resistivity surveys depend on different physical properties than seismic or sonic surveys, the two taken together can provide important cross checks. If a system could perform multiple survey methods, better information about, for instance, the shallow subsurface could be obtained with a single multi-method survey.

Furthermore, there is developing interest in repeating surveys to observe changes that may occur in the subsurface, such as seasonal changes in groundwater level, effectiveness of subsurface pollutant remedial activities, and soil movement and water

penetration under roadways, bridges, and dams. This usually requires that equipment be in place for long periods of time and necessitates frequent visits to the survey sites by geophysical technicians to monitor changing subsurface conditions.

5 The present state of the art does not provide an effective way to remotely manage field equipment and monitor survey data, much less monitor data in real-time. Field personnel must travel to the sites, perform the survey, collect the data in a temporary data storage device, and carry the data to a data center for processing and analysis. This may be done monthly, weekly, or more frequently depending upon how quickly the subsurface feature being monitored changes.

10 During a survey, one may discover that equipment performance has degraded or some components are not performing at all. Presently, he or she must then contact a service technician by telephone to report the problem, resulting in lengthy and sometimes confusing attempts to diagnose the problem and repair the equipment. The result is that the service technician must travel to the site to diagnose the problem, or the equipment
15 must be sent to a service center for diagnosis and service.

Often, when equipment is returned to a service center, the equipment is found to be in satisfactory condition, and the problem remains at the site. This results in excessive "down-time" in the field and unplanned and excessive costs. If a means to remotely manage survey equipment and collect survey data were incorporated into a survey
20 system, significant operational and cost advantages would accrue. For example, electrical resistivity strategies could be changed remotely and interactively from Dipole-Dipole to Wenner/Leed by the investigator. Measurement parameters such as injection

current magnitude and period, survey frequency and method could be changed. Remote tests and diagnostics could be performed on all equipment to determine their level of operability and specific equipment requiring service.

5 A further disadvantage of present survey systems, in particular systems for the electrical resistivity, is the lengthy time required to perform a typical survey. Time limitations are due primarily to internal instrument noise caused by conductive coupling between cable conductors and connector pins (signal to noise ratio). The number of receivers active during a survey event is currently limited by the number of conductors in a cable. If a system were to eliminate the coupling noise and to remove the limitations
10 on the number of receivers, shorter survey times could be achieved—from hours to minutes for a typical 100-survey probe system. This could result in survey crew labor savings and overall greater productivity.

Present electrical resistivity survey systems require multi-conductor cabling to simultaneously carry high voltage and low level analog potential signals. Multiple cable
15 segments with integrated survey probes are connected together in the field in preparation for surveys. The cable segments must be connected with very careful attention to the order in which they are connected. Whether passive survey probes or intelligent survey probes, incorrect connections result in unintelligible and useless data. If an electrical resistivity survey system did not require cables to simultaneously carry high voltage and
20 low voltage signals, data accuracy would be improved. Cables could be lighter and easier to handle in the field. Furthermore, if it were not required that cable sections must be connected in specific order, connection errors, survey errors, and field set-up time could

multi-method shallow subsurface exploration system capable of performing synchronized analog to digital conversion of AC and DC electrical signals detected at 2 to 1000 or more points in a probe survey array. The signal conditioning and A/D conversion can be performed locally at an intelligent survey probe which contains electrical components
5 such as a microprocessor, signal conditioning circuitry, short term energy storage, switching devices, and connections to one or more sensors and transducers associated with different exploration survey.

Embodiments of the invention provide a wireless link or, optionally, a conductor cable bus link for two-way communication between one or more survey controllers and
10 survey probes. Each means (wireless or conductor cable bus) may be most suitable for a particular embodiment and may depend on the type of survey to be performed. Each means requires the spatial location of stimulus and measurement probes.

In cable bus embodiments, a time-multiplexed conductor cable system can be used for two-way communication between a survey controller and each of multiple
15 survey probes, rather than by wireless means. The conductor cable system can provide for delivery of power from the survey controller to the survey probes.

In one embodiment, each survey probe is assigned a 4-byte serial number or other identifier. In one embodiment, such an identifier can be assigned at the time of manufacture. In cable bus embodiments, the serial number or other identifier can be
20 obtained as the survey probe is connected to the cable in the field prior to survey events, or at any time after connection to the cable bus. This eliminates the requirement to connect survey probes in a specific order. Accordingly, a survey probe can be accessed

by a command message from the survey controller using either the survey probe's serial number or a field-assigned access number or other identifier. A serialized access number is one convenient way to access survey probes from the survey controller, although it will be recognized that other techniques could be used.

5 Assignment of access numbers can follow a startup protocol. When a survey probe is first connected to a survey controller cable, it can receive power, initialize and send a data message to the communication data bus announcing its serial number or identifier. The survey controller can respond by sending a message to the survey probe serial number or identifier found in the incoming message, assigning an access number to
10 the survey probe. The survey probe can accept the access number, acknowledge execution of the command, and enter an idle or standby state. This process can continue for each survey probe. In one embodiment, this process can continue until the operator signifies to the survey controller that the last survey probe has signed in or until the signing-in of the last probe is detected automatically.

15 In another startup protocol, one or more survey probes are connected on a survey controller cable and the cable is terminated on a survey controller. The survey controller applies power to the cable causing each survey probe to execute a start up protocol, disconnect its down-stream neighbor from the signal bus, and enter an idle state. Downstream refers to survey probes toward the end of the cable and away from the
20 survey controller. The survey controller transmits a special broadcast command to the cable to command any survey probe in idle state to report its serial number code. Only the first survey probe receives the command (all the other down-stream neighbors are

disconnected) and responds with its survey probe serial number code. The survey controller receives the serial number code from the first survey probe and can respond with a command to the first survey probe to accept a different identifier as its access code. The first survey probe can change its access code to this different identifier, exit
5 from the idle state and proceed to state S1. The first survey probe can reply to the survey controller confirming its access code and connects the second downstream survey probe to the cable. At this point in the process, the only survey probe in the idle state is the second survey probe. The cycle continues until no further responses are received from the special broadcast command, which result in the reporting of serial number codes. In
10 this manner, each probe is automatically identified, associated with a unique identifier, and its order relative to the other probes (first probe, second probe, third probe, etc.) is determined. As will be recognized by those having ordinary skill in the art, this process can save a significant amount of time because the survey controller can now automatically determine probe order and identifiers during, for instance, a startup
15 protocol.

In one embodiment, the investigator, prior to starting the survey, manually records the positions of all connected survey probes according to their respective identifier. The survey controller knows the access identifier and the order of each survey probe in the cable network and is prepared to execute surveys.

20 In a different embodiment, the position of each survey probes is determined wirelessly by measuring its distance from two or more reference point locations generally positioned on the survey site.

In a wireless embodiment, one can determine the spatial location of each survey probe using radio, sonic or optical position transceivers. Each survey probe measures its distance from one or more position-transmitter sources, one of which may be the survey controller. These measurements are transmitted to the survey controller. From these
5 measurements, the survey probe calculates its distance from each position transmitter source and reports this information and its identifier to the survey controller. The survey controller can use this information to control the survey. The survey controller can assign a unique access number or other identifier to each survey probe.

Another embodiment of a wireless technique for determining spatial position of a
10 survey probe uses an RFID transponder, such as Texas Instruments RI-TRP-B9WK, associated with each survey probe. The transponder is responsive to interrogation by a an RFID reader such as the portable TI Series 2000 reader system. A differential GPS receiver is also used, and this receiver can be integrated with the RFID reader. The RFID reader can be placed near a probe for interrogation. The reader interrogates the RFID
15 transponder and receives the transmitted data. The data, unique to each transponder, is received and combined with the reported Differential GPS longitude, altitude, and latitude measured at the probe. This data can be stored in the RFID memory until communicated to the survey controller.

In a wireless embodiment for determining spatial position using the known
20 position transmitter positions, the survey controller can also calculate relative positions of survey probes and convert them to standard longitude, latitude, and elevation coordinates, or another convenient coordinate system, for each survey probe. Generally, two properly

positioned position transmitters are required for survey probe location in a two dimensional space, and three are required for locating survey probes within a three dimensional space.

5 In wireless embodiments, each survey probe thereafter may be accessed by either its serial number or access number in subsequent message packets or by way of other wireless transmission techniques known in the art.

10 In different embodiments, probes can be connected to survey controllers by cable for transmission of operating power, stimulus (power to energize stimulus transducers, such as current injection) as required by the survey controller's survey program, and for signal measurement reference. Two conductors can carry power to the survey probes for charging one or more temporary energy storage devices, the electronics, and relays during a survey dwell time. These two conductors can also carry high energy to power stimulus injectors during a survey event and complete the circuit to a high energy power supply. It is to be noted that passive survey events can be performed by measuring
15 natural induced potentials without the injection of a stimulus into the earth. The third conductor can provide a reference for potential measurements during the survey event, and, in conjunction with one of the power conductors, a data communication bus (*e.g.*, a bus between survey events).

20 According to different embodiments, electrical resistivity measurements can be made by applying a voltage to cause a measured current flow between two or more stimulus points on a surface such as the earth's surface (*e.g.*, stimulus points). Differences of the induced voltage potentials between one or more measurement points

can be determined. The potential measurement data and current flow data and probe positions can be processed by the application of known mathematical processes, typically reduced to computer programs. Using the mathematical processes, the resistivity of a subsurface can be deduced or inferred.

5 In reference to 3-conductor embodiments described above, the third conductor can provide for a common potential to which all or a number of survey probes measure induced potentials. The third conductor can be electrically-connected to some point in the earth or on the current injection source. Since survey probe measurements can be made relative to this common potential, the potential difference between participating
10 survey probes can then be calculated, and the resistivity determined as just previously described.

 The third conductor can also provide for measurement of the potential difference only between two adjacent survey probe points. Survey probes can measure potentials relative to that of a specified neighboring survey probe. Segments of the third conductor
15 can be switchable to provide the connections between the survey probes, operating to provide a reference voltage during the survey event. This reference can also be switchable to provide a common reference voltage to all survey probes.

 Different embodiments also provide the ability to measure the potential change of a measurement point due to an injection stimulus. The measurement point can be
20 measured prior to a current injection. This same point can be again measured after the injection stimulus. The difference is taken. This difference is the potential change due to the injection stimulus. The survey controller can signal each survey probe a

predetermined time prior to stimulus injection. At this time after a programmed delay, each survey probe can sample and hold the data collected. In different embodiments, each probe can delay for a pre-programmed delay time after a signal has been received from the survey controller, before the probe begins to sample. In one embodiment, the default delay time is zero. However, each probe may be setup by the survey controller with a different delay-to-sample.

In reference to 3-conductor embodiments described above, the third conductor can carry data (*e.g.*, via data packets or other known means) to and from survey probes and a survey controller during, *e.g.*, the survey dwell time that is between survey events. For example, data packets may contain commands from the survey controller which are decoded by the accessed survey probe to set-up or prepare for a survey event, or it may be a command to the accessed survey probe to transmit survey data from a previous survey event.

During a survey event, the third conductor can be switched to a reference voltage, such as earth ground by the survey controller. Reference ground can be used by each survey probe as a reference signal for sensor signal measurements. Simultaneously or at a different time, the survey probe can disconnect itself from the two power conductors and obtain operating power from its energy storage device. In one embodiment, the energy storage device can be a 0.1 Farad capacitor manufactured by AVX Corp., part number BZ015A104ZHB, or equivalent. The value of the capacitor may differ for different embodiments. This capacitor can be charged during the dwell time and contains sufficient energy to operate the survey probe during the survey time. One advantage of

using a capacitor is that it does not need replacement as do batteries, it eliminates the maintenance due to battery replacement, it eliminates the need for battery charging circuitry, and it eliminates environmental issues associated with disposing of large numbers of batteries. Use of an internal energy source such as a capacitor beneficially
5 allows for the isolation of the survey probe from the survey controller during the survey event and significantly reduces noise. Another embodiment isolates all survey probes completely, connecting only to an adjacent survey probe and recording the difference potential measured between the two survey probes.

In conventional systems, dc power is generated and delivered to all probes
10 directly from a central power source and is usually regulated at individual probes. This dc power line, even though filtered at each probe, typically picks up radiated noise from the environment due to long cable runs. Each probe therefore contributes filtered noise to the conducted digital noise to the dc power distribution conductors to all other probes. Any ripple or transient noise induced by the central power supply contributes noise.
15 Although conventional practice involves filtering the dc power line with high pass filter capacitive networks, the filtered noise is applied to the ground circuit of each probe. This noise finds its way into the measurements of all other probes.

Another source of noise can be high voltage injection current conductor, which is, in interest of economy, usually carried in the same cable with (a) the dc power conductor,
20 (b) the dc power ground, (c) the high voltage return conductor, (d) the signal conductors and (e) the signal return conductor common to all signal conductors. Also there can be large current and high voltage transients during any injection period, which can couple

noise to the micro-volt level signals on signal conductors, significantly decreasing the signal to noise ratio of the measurement and requiring complex filtering processes and circuitry to minimize the deleterious effects. This occurs during the period that the very sensitive measurements are being made.

5 Embodiments of this disclosure virtually eliminate external noise problems by having all (or a subset of) probes isolate themselves from these external noise sources during a measurement period. Furthermore, digital data representing the measurements can be transmitted during a dwell time and are virtually insensitive to noise on the cable.

10 In embodiments of the disclosure, signals can be conditioned and digitized directly from conductive stakes or other transducers such as motion, sound, magnetic, or gravimetric transducers properly coupled to *e.g.*, the earth surface or boreholes through the surface.

15 Prior to a survey event, each survey probe can receive a setup command data packet from a survey controller specifying its function during the survey event as mentioned above. Any survey probe can be adapted to function by command as a signal receiver and processor, or stimulus injector. For example, in the case of the electrical resistivity method configuration, a survey probe can be adapted to function as an electrical current injector.

20 In one embodiment, survey probes receive a first synchronizing signal from a survey controller and each probe proceeds to configure itself according to the setup command it received from the survey controller by operating switches and initializing a correct program to perform the tasks and selecting the signal source for the A/D converter

in preparation for the survey event.

In this embodiment, survey probes receive a second synchronizing signal and those survey probes assigned the task of stimulus or scheduled injection proceed to inject the stimulus into the surface, which in one embodiment may be according to a pre-
5 programmed time delay and period. All survey probes assigned the task of receiver can delay for a programmed time period and commence to digitize and filter the signals received from the connected sensors, according to prescribed processing algorithms. Survey probes can accumulate processed signal data until requested by the survey controller. In one embodiment, simultaneous to receiving the second synchronizing
10 signal, survey probes assigned the function of stimulator injector can direct high power voltage through their switches to their corresponding connected stimulators. The stimulator might be a magnetic hammer for sound or seismic method, or a metal stake for current injection for electrical resistivity method. Other stimulators known in the art can also be used.

15 At the conclusion of a survey event, each survey probe can enter an idle mode and reconnect power and one or more communication conductors to the energy storage device and communications device, respectively, in preparation for receiving a message from a survey controller to report its results of the survey. A survey controller program then can optionally command each survey probe to report the data it captured during the survey
20 event. If no such command is received by a survey probe, it can store the results for future delivery at the request of the survey controller. If another survey event is to occur, the survey controller can send new setup information to each survey probe in preparation

for the next survey event, and the cycle can be repeated.

In one embodiment, access to the survey controller is provided by a local or remote Internet browser or by way of another computer network. A web server can be embedded within a survey controller, and the server can include software to interact with survey probes. A local or remote browser can effect secure download of applications programs and diagnostic software to specific survey probes. The survey controller can accept uploads from the remote browser to initiate built-in test software, to report key system operational data, to collect survey data, update information and survey instructions, and/or other functions with which the survey controller software has access to.

In one embodiment, communication server function is provided in one or more survey controllers in the survey environment, and the one or more controllers are connected to a remote network. Connection to the remote network may be by satellite or terrestrial means. In one embodiment, primary communication can be accomplished between survey controllers and any communicating device accessible via the Internet by using techniques known in the art of communications such as techniques the Hypertext transfer protocol(HTTP) and hypertext markup language(HTML), and/or (XML) Extended Markup Language. Each survey controller can be adapted to facilitate real-time access between a survey controller and a remote device upon access of a particular page, script, or function.

In one embodiment, executable content is embedded in one or more HTML pages so that when a page is loaded onto an HTML browser after being accessed, the

executable content starts running automatically. The executable content can act to perform specified data transfer operations between the browser and one or more survey controllers. Additionally, survey controllers' operating systems, upon detection of an urgent local event, can request or initiate a session with an appropriate, predetermined
5 remote terminal device or server for service.

In one respect, the invention involves a system for measuring a property of a surface, the system including a plurality of survey probes and a survey controller. Each of the of the survey probes has a unique identifier, and the survey controller is configured to automatically poll the survey probes to obtain each identifier and determine a relative
10 order the probes. In one embodiment, polling can occur once during a startup protocol, although it will be understood that it could occur at different times/frequencies throughout any given process. In one embodiment, the polling may take place as follows: each survey probe can be configured to (a) disconnect a downstream neighbor survey probe and enter an idle state; (b) report its unique identifier to the survey controller if in
15 the idle state and in response to a polling command from the survey controller; and (c) change to a state other than the idle state after reporting its unique identifier. In other embodiments, different steps may be taken that are suitable to convey unique identifiers to the survey controller and to convey relative ordering of the probes. This, of course, greatly improves the state of the art in which determination of probe ordering is typically
20 handled manually in a time consuming manner. The survey controller can be configured to assign and transmit a different, unique identifier to each survey probe. The survey controller and survey probes can be configured to communicate wirelessly. The survey

controller and survey probes being can be connected by a first number of conductors, the survey probes can be configured to perform a second number of simultaneous measurements of the surface, and the second number need not be limited by the first number. Accordingly, the system can be set up to do a number of simultaneous
5 measurements independent of the number of conductors connecting probes to the survey controller. For instance, although probes may be connected, in one embodiment, to the survey controller using three conductors, far more than three simultaneous measurements can be performed. The survey controller can be remotely accessible through a computer network for remote control of the survey controller and the survey probes. In one
10 embodiment, this computer network is the Internet, although other networks can be utilized as well. The survey probes can be connected to the survey controller through three conductors, two conductors supplying power and a third conductor acting as a communications bus.

In another respect, the invention involves a system for measuring a property of a
15 surface, the system including a survey controller and a plurality of survey probes that are configured to: (a) collect signals associated with the surface; (b) digitize the signals to form digital data; and (c) store the digital data for later transmission to the survey controller. The survey probes can be configured for performing both electrical and seismic measurements, and the signals can include seismic or electrical signals. The
20 signals associated with the surface can include signals that are generated in response to the surface being stimulated. For example, the signals can be in response to electrical and/or seismic stimulation. In other embodiments, the signals can result from a passive

state of the surface. The survey controller and survey probes can be configured to communicate wirelessly. The survey controller can send data to individually program survey probes to generate a stimulus simultaneously or according to another programmed timing scheme. The stimulus can include injection of current. The survey controller can
5 send data to individually program survey probes to form digital data and store the digital data according to a programmed timing scheme. The survey controller and survey probes being can be connected by a first number of conductors, the survey probes can be configured to perform a second number of simultaneous measurements of the surface, and the second number need not be limited by the first number. Such an embodiment and
10 its advantages are described immediately above. The survey controller can be remotely accessible through a computer network (*e.g.*, the Internet) for remote control of the survey controller and the survey probes. The survey probes can be connected to the survey controller through three conductors, two conductors supplying power and a third conductor acting as a communications bus.

15 In another respect, the invention involves a system for measuring a property of a surface, the system including a survey controller and a plurality of survey probes that are configured to: (a) collect signals associated with the surface; and (b) sample and hold the signals for later transmission to the survey controller.

20 In another respect, the invention involves a system for measuring a property of a surface, the system comprising a survey controller and a plurality of individually-addressable survey probes, where the survey controller is configured to: (a) transmit a first signal to individually program survey probes to conduct one or more steps for

measuring the property of the surface and (b) transmit a second signal to cause survey probes to conduct the one or more steps according to a timing sequence. Accordingly, the survey controller can send programming instructions to individual probes and then send instructions to carry out the program. Such instructions can be sent remotely over a
5 computer network such as the Internet. Such embodiments provide for a level of flexibility and convenience not known in the art. The survey controller and survey probes can be configured to communicate wirelessly. The survey controller can further be configured to transmit a third signal to diagnose survey probes. This, among other things, eliminates or reduces the need for on-site technicians to perform diagnostics on
10 probes. The survey controller and survey probes can be connected by a first number of conductors, the survey probes can be configured to perform a second number of simultaneous measurements of the ground, and the second number need not be limited by the first number. As mentioned above, the survey controller can be remotely accessible through a computer network for remote control of the survey controller and the survey
15 probes. The survey probes can be connected to the survey controller through three conductors, two conductors supplying power and a third conductor acting as a communications bus.

In another respect, the invention involves a system for measuring a property of a surface, the system including a survey controller and a plurality of individually-
20 addressable survey probes, where the survey controller is configured to transmit a diagnostic signal to individual survey probes to diagnose the individual survey probes.

In another respect, the invention involves a system for measuring a property of a

surface, the system including a survey controller and a plurality of survey probes whose position relative to one another is automatically determined. This advantageously allows for much more efficient measurement techniques because the system can itself determine physical relative and/or absolute locations of probes. In one embodiment, a transmitting
5 beacon is provided, and the position is determined using a signal from the transmitting beacon. In another embodiment, a radio frequency identification (RFID) system is coupled to the probes and a Global Positioning System (GPS) is used. The position is determined by combining identification information from the RFID system with positional location from the GPS. In another embodiment, the RFID system can alone be
10 used to identify individual probes and report that information, including information about the relative ordering of the probes, to the survey controller. The survey probes can be in motion. In such an embodiment, even if the probes are being, e.g., pulled behind a boat, their relative positions can be continuously determined. This offers great advantages over the current state of the art.

15 In another respect, the invention involves a system for measuring a property of a surface, the system including a plurality of survey probes and a survey controller configured to supply power to the survey probes using a power conduit. The survey probes automatically electrically disconnect from the power conduit while measuring the property and operate using an internal source of power when disconnected to reduce
20 noise. This reduction of noise offers great advantages over the current state of the art such as improved accuracy of measurements.

In another respect, the invention involves a system for measuring a property of a

surface, the system including a plurality of survey probes and a survey controller configured to program the same survey probes for seismic or electrical measurements of the surface. Accordingly, one system of survey probes and controller(s) can be used not only to do electrical resistivity measurements, but can also be used to perform seismic measurements. Currently, two separate systems would be necessary. Those having ordinary skill in the art with the benefit of this disclosure will recognize that even additional different types of measurements can be performed with a single system. Allowing such flexibility is, among other things described here, the ability to individually program survey probes to follow instructions dictated by the survey controller (*e.g.*, to follow instructions to produce a certain type of stimulus and/or to receive data according to specified timing schemes). Each other embodiment of this disclosure can also exhibit this significant advantage, allowing for different types of properties of a surface to be measured with different measurement techniques (*e.g.*, but not limited to, electrical and/or seismic) using a single measurement system that is configured to be programmed for different types of measurements according to different timing schemes and the like.

In another respect, the invention involves system for measuring a property of a surface, the system including a plurality of survey probes and a survey controller that is remotely accessible through a computer network for remote control of the survey probes, the remote control including: (a) remote initiation of a measurement of the property of the surface and (b) remote collection of data from a measurement of the property of the surface. In one embodiment, the network can be the Internet. The remote control can further include remote processing of data from a measurement of the property of the

surface. The remote control can further include remote diagnostic testing of survey probes. The computer network can include a wireless network.

In another respect, the invention involves a system for measuring a property of a surface, the system including a plurality of survey probes and a survey controller
5 configured to program the plurality of survey probes to simultaneously apply a stimulus to the surface in an arbitrary pattern. In conventional systems running electrical measurements, point source injection of current is the norm. Using techniques of this disclosure, however, one is not limited to such point injection. Rather, one can simultaneously inject current using several different probes in an arbitrary pattern to
10 create, e.g., a line-source injection, a traveling pattern, etc. In one embodiment, the pattern includes a line pattern, and in another embodiment, the pattern includes a moving wave pattern. Many other patterns and schemes can be used as will be recognized by those of ordinary skill in the art to perform several measurements that, until now, have been effectively impossible.

15 In another respect, the invention involves a method for measuring a property of a surface, the method including: collecting signals associated with the surface using a plurality of survey probes; digitizing the signals using the plurality of survey probes to form digital data; and storing the digital data using the plurality of survey probes for later transmission to a survey controller. The method can also include: polling the survey
20 probes using the survey controller to automatically: (a) obtain an identifier of each survey probe; and (b) determine a relative order of the survey probes. The survey controller and survey probes can be connected by a first number of conductors, and the

method can also include performing a second number of simultaneous measurements with the survey probes, the second number not being limited by the first number. The method can also include: controlling data acquisition, data processing, or data collection associated with the survey controller remotely over a computer network. The survey probes can be connected to the survey controller by one or more conductors that supply power, and the method can also include automatically disconnecting the survey probes from the one or more conductors while measuring the property and operating using an internal source of power when disconnected to reduce noise. The method can also include automatically determining the relative position of the survey probes. The relative position can be determined using (a) a transmitting beacon or (b) a radio frequency identification (RFID) system and a Global Positioning System (GPS). The method can also include performing a seismic and electrical measurement of the surface using the same survey probes.

In the embodiments described here, the term "surface" is broad and encompasses any surface or sub-surface. A surface can include surfaces of water, ground, underwater surfaces, man-made surfaces, borehole surfaces, borehole subsurfaces, etc. As used herein, "automatically" distinguishes an act done manually by, for instance, a technician. In preferred embodiments, "automatic" tasks are done via computer instructions that dictate certain tasks be done by one or more computers or computer-operated hardware. As used in the claims, the indefinite articles "a" and "an" mean one or more unless explicitly noted otherwise. For instance, although claims may state "a" survey controller, it will be understood that the claim encompasses and contemplates situations in which

more than one controller is used. The term "comprising" in the claims is an open-ended term. "Couple" means a direct or indirect connection.

Other advantages and features of embodiments of this disclosure will be apparent with reference to the following drawings and the additional description that follows.

5 **BRIEF DESCRIPTION OF THE DRAWINGS**

 The drawings accompanying and forming part of this specification are included to depict certain aspects of the invention. A clearer conception of the invention, and of the components and operation of systems provided with the invention, will become more readily apparent by referring to the exemplary, and therefore nonlimiting, embodiments
10 illustrated in the drawings, wherein like reference numerals (if they occur in more than one view) designate the same or similar elements. The invention may be better understood by reference to one or more of these drawings in combination with the description presented here. It should be noted that the features illustrated in the drawings are not necessarily drawn to scale.

15 FIG. 1 is a drawing depicting a wide area network of multiple survey controllers connected through the Internet or locally according to embodiments of this disclosure.

 FIG.2 is a drawing illustrating an example sequence for a client browser to establish a session with an embedded web server survey controller according to embodiment of this disclosure.

20 FIG. 3 is a block diagram of an example exploration survey system having an array of survey probes connected by cable to a survey controller according to embodiments of the present disclosure.

FIG. 4 is a block diagram of a survey probe according to embodiments of the present disclosure.

FIG. 5 is a plan drawing depicting a cable interconnected array of survey probes arrayed and connected to a survey controller according to embodiments of the present disclosure.

FIG. 6 is a horizontal section through the earth showing vertically arranged survey probes in a borehole interconnected by cable segments according to embodiments of the present disclosure.

FIG. 7 is a horizontal section view of a linear array of survey probe mounted on conductive stakes inter-connected by cable segments according to embodiments of the present disclosure.

FIG. 8 is a view of an embodiment of a survey probe with cables and connectors according to embodiments of the present disclosure attached to a conductive stake in the ground.

FIG. 9 is a drawing depicting multiplexing of power to survey probes according to embodiments of the present disclosure.

FIG. 10 depicts a system synchronizing signal derived at each survey probe according to embodiments of the present disclosure.

FIG. 11 depicts operating timing of system relays according to embodiments of the present disclosure.

FIG. 12 is a schematic of a Survey Controller Program in accordance with embodiments of the present disclosure.

DETAILED DESCRIPTION OF EXAMPLE EMBODIMENTS

Referring now to the drawings it will be understood that the illustrations and accompanying text are provided to describe example embodiments and are not intended to limit the invention herein. It is the claims that define the invention.

5 Certain aspects of this disclosure focus on the electrical resistivity survey method managed by a local or remote browser. It will be clear to those having ordinary skill in the art that the following description applies equally well to other survey method applications known in the art. Neither this disclosure nor the claims (unless explicitly stated otherwise) are limited to a particular type of survey method such as electrical
10 resistivity.

 The World Wide Web is a collection of servers of the Internet that use the hypertext transfer protocol (HTTP). HTTP is a known application protocol that provides users with access to files, which can be in different formats, such as text, graphics, images, sound and video using a standard page description language, HTML. HTML
15 provides basis document formatting and allows the developer to specify links to other servers and files therein. Use of an HTML compliant client browser involves specification of a link having a URL. Upon such specification, the client makes a request to the server identified in the link and receives a web page, basically in document format, according to HTML, in return. HTML provides exceptional freedom in creating
20 graphics/text/graphic images and associated audio between servers and client browsers. HTTP and HTML allow complex services to be accessed by clients having a minimum amount of hardware sophistication.

Turning now to FIG. 12, a typical survey controller program 77 (*see*, FIG. 3) for a survey controller 1 embedded microprocessor 21 is shown. The survey controller program includes a network connection 108 having multiple hardware and/or software ports or addresses, 32, 34, 110. The survey controller program has a controller and software tasks including survey manager 118, survey probe manager 115, power source control 116, cable multiplex control 117, system diagnostic manager 120, software download manager 119, associated with RAM/flash memory cooperating to run under operating system 87C, server or server task 112 in cooperation with the network connection 108 which provides access to the survey controller 1 server from a local Client Terminal browser 5 (*see*, FIG. 1) or remote Client Terminal browser 7 (*see*, FIG. 1) on a local network or the internet. The local browsers 5 are typically able to access the server task 112 of the survey controller 1. Preferably, the browsers 7 may also access the server 112 of survey controller directly. A software task is defined very broadly to include both separate and integrated software embodiments which may or may not run concurrently with other software.

An embedded function 87B can be integrated with a page 87A. The page 87B may be a basic HTML page, script, function or like program. The embedded function may be attached to a header of the page 87A or otherwise associated with the page wherein one of two events occurs when the page is accessed. First, the page 87A along with the embedded function 87B can be delivered to the browser that accessed the server and page. Alternatively, the embedded function 87A can be adapted to run on the server from which the page was accessed, even though the page is delivered to the appropriate

browser. In the first case, the embedded function can be adapted to run at the browser. In the second case, the embedded function can run at the server that the browser accessed.

In one embodiment, the embedded function is any executable content, such as
5 Java applets. The executable content may be one or more small applications that conform to a restricted set of programming standards for running on browsers. When the embedded function is sent to the browser upon accessing a page, the function can be run at the browser to facilitate connection back to a specific server and server location. In another embodiment, the embedded function can run at the server and act to keep the
10 existing connection open as well as to periodically send updated HTML pages. This latter technique places fewer demands on a browser's application capabilities but is less flexible. The remote browser or client may store data and determine how often to update or to request an update. The parameters relating to periodic updates may be stored locally at the remote browser, or may be downloaded to the survey controller. In the
15 latter case the server task 112 may take the responsibility of periodically sending data to the remote browser without a request from the remote browser.

In one embodiment, a user at the browser 5 or 7 starts a browser application and connects to a homepage at a site's uniform resource locator (URL) address. An example process, where embedded functions are actually transferred to the browser from the
20 accessed server, is outlined in FIG. 2. It will be understood that FIG. 2 serves to illustrate several other embodiments as well. In one such embodiment, communications are provided between the survey controller 1 at the survey site and a browser 5 or 7,

preferably running on a client PC. For example, the browser may be located at a remote site on the Internet or other similar network in addition to being located at the survey site.

Initially, a user at the browser 5 or 7 can start a browser application and connect to a homepage at a site's uniform resource locator (URL) address (block 101). An HTTP
5 server 1 having the URL address at the survey controller can deliver a home page for a site asset management system to the browser 7 (block 102). The user at browser 5 or 7 can select a defined link on the homepage to access and monitor a select function in the survey controller (block 103). In one example, the selected function can be the survey controller's completed survey result file (block 106). The server can generate a status
10 page containing executable content, *e.g.* a Java Applet, and deliver the page and the executable content to the client (block 105). For ease of understanding, this executable content can generally be referred to as the embedded function.

The client's browser 5 or 7, can load the page from the survey controller 1 and run the embedded function (executable content), which can immediately connect back to
15 the selected service device, preferably using a separate address and protocol (block 105). The device will accept the connection initiated by the embedded function and begin delivering status data (in one embodiment, in real time) to the client browser 5 or 7.

In addition to monitoring selected information at various ports and addresses at the selected device server, the connection between the browser and the selected device
20 may provide for any type of uploading or downloading of information, software, or control data to monitor, access, and otherwise reconfigure any portion of the survey site addressable and accessible through the server.

For example, the client browser 5 or 7 may download a new configuration or software upgrade for survey probes, survey controller, or any other programmable device or data source addressable and accessible through the server. Additionally, the browser may simply gather completed survey files or in-process survey data.

5 Figure 3, another example embodiment, includes a survey controller 1 connected by cables 11 including, in a preferred embodiment, not more than 3 conductors, to an array of autonomous survey probes 12. In other embodiments, more or fewer than 3 conductors can be used, as will be recognized by those having ordinary skill in the art with the benefit of this disclosure.

10 In the example embodiment of FIG. 3, a survey event is created when an electrical current is forced through the earth between two or more survey probe 12 electrodes 50, and when two or more different survey probes 12 sense, digitize, and store the induced potentials detected by their respective electrodes 50. PS 22 and associated circuitry provide the electrical current. The timing and value of said electrical current is
15 prescribed by Survey Control Program (SCP) 77. The survey event is completed when each different survey probes 12 report the digitized potential measurements to Survey Controller 1, or when Survey Controller Program proscribes that survey probes store the measurements for later reporting.

20 Referring now to FIG. 9, the horizontal axis indicates the time sequence of voltage transitions on conductor 45. The transitions are fixed in sequence but vary in time as operably prescribed by CMC 117, and are labeled T^0 , T^1 , T^2 , and T^3 . State S0 begins with time T^0 and ends with T^1 , state S1 begins at time T^1 and ends at time T^2 ,

state S2 begins at time T^2 and ends with time T^3 , state S3 begins at T^3 and ends at time T^0 . The vertical axis represents the magnitude of voltage measurable on cable conductor 45 relative to cable 46.

Now also referring to FIG. 3, during state S0, CMC 117 operates to de-activate
5 relay coil 18A, connecting communication transceiver 27 to cable 11, conductor 47
through relay 18B contact pair B-A. SPP 78 of all survey probes 12, cooperatively de-
activate relay coils 90, thereby connecting transceivers 54 to conductor 47 through relays
90A contacts A-B, providing a communication link between SPP 78 and SPM 115. SPM
115 and SPP 78 cooperatively operate to exchange messages, to setup for the next survey
10 event, to report measurement data, and other messages necessary for coordination
between survey controller 1 and survey probes 12.

At the beginning of state S1, PSC 116 operates to apply power to all survey
probes 12 through conductors 45 and 46. Next, SPM 118 operates to initialize each
participating survey probe 12 in preparation for collecting survey data from each "sensor"
15 survey probe 12 and preparing for the next survey event.

PS 26 is a programmable power supply provided with conductor 61 for current
return through relay 18DE, conductor 109 connecting to power gate 25 and to
communication transceiver 27. Data bus 37 is provided for exchange of digital command
and data between PSC 116 and PS 26. PS 26 is adaptable to receive commands from
20 PSC 116, and operates to adjust output voltage to values prescribed by PSC 116 and to
report actual output voltage values to PSC 116. Signal line 36 is provided for CMC 117
to signal Power Gate 25. CMC 117 is operable to signal Power Gate 25 to permit said

current flow during state S1 and to block current flow during states S0, S2, and S3. Power Gate 25 is adaptable to respond to signals from control line 36 to block or permit current flow from PS 26 to meter 23. Data bus 34 is provided exchange of digital information between PSC 116 and programmable meter 23. Conductor 88 is provided to
5 connect the output of Gate 24 and Gate 25 to meter 23. Meter 23 is adaptable to sensing, measuring, and digitizing the electrical current magnitude flowing from conductor 88 to conductor 45 and responsive to PSC 116 to report said digitized value to data bus 34 upon command by PSC 116. During S1, meter 23 signals PSC 116 that current flow has reached a prescribed value indicating that C1 energy storage devices are charged and that
10 survey probes 12 are prepared to receive setup assignments for the next survey event to occur during the following state S3. SPM 118 then operates to send set-up command messages to each survey probe 12 prescribing each survey probe's function to be performed during the survey event.

For the purpose of better understanding the present invention, the following
15 scenario is presented as a simplified example of the processes which take place during state S1. SPM 115 commands each survey probe 12 to perform specific functions for the duration of the survey event. The functions are current injection, current receiver, and ground voltage potential sensor. For example, survey probe 12 "A" is assigned to current injection function, survey probe 12 "B" is assigned current receiver function to receive
20 injection current, completing the path to PS 22 through the earth during the survey event. Survey probes 12 "C", "D", "E", "-Z". are assigned ground voltage potential sensors to sense, digitize, and record voltage potentials appearing at their respective electrodes 50 or

48, and are hereafter known as sensors.

Using signal line 36, CMC 117 signals gate 25 to close. Closure of gate 25 is detected by circuit 38 which signals SPP 78 over conductor 52. SPP 78 detects that the system is in state S2. SPP 78 of each survey probe proceeds to perform their respective
5 setup instructions received from CMC 117.

Paths through relay contacts are specified by the numerical relay actuator number following by the contact pair completing a circuit. For example, 18BA refers to the contacts B and A of relay actuator 18.

SPP 78 operates relay actuator 18, to establish a return path from cable conductor
10 46 through 18DF, conductor 55, to PS 22 return 55. Operation of relay actuator 18 also establishes a connection from cable conductor 47, connector 79, 18AC, conductor 40, to reference ground.

To continue the example, survey probe 12 "A" is assigned injection function. The associated SPP 78 operates relay actuators 89, 91, 90, and 92 through port
15 connections to microprocessor 69, establishing a current path from cable conductor 47, through relay contacts 89AC, 91AC, conductor 85, contacts 92AC, connector 74 to electrode 50. Survey probe 12, and SPP 78 become idle until state S3 is detected by circuit 38, signaling SPP 78 through conductor 52. "A" survey probe 12 is thereby prepared as current injector.

20 Survey probe 12, "B" is assigned current return function. The associated SPP 78 operates relays actuator 89, 90, 92 through port connections to microprocessor 69. These relays establish a return current path from electrode 50, through connector 74, through

relay contacts 92AC, conductor 85, relay contacts 91AB, 89FD, connector 70, cable conductor 46, connector 79, relay contacts 18DF, conductor 55, to PS 22 return 55. Survey probe 12, and SPP 78 become idle until state S3 is detected by circuit 38 and signaled to SPP 78 through conductor 52. "B" survey probe 12 is thereby prepared as
5 current receiver.

Survey probes 12 "C", "D", "E" -"Z" are assigned "sensor" function. The associated SPP 78 operates relay 89, and 90 to establish a circuit from electrode 50, connector 74, contacts 92AB, conductor 80, through signal conditioner 64, to signal line 49 to input multiplexor 65 of microprocessor system 51. SPP 78 operates to provide
10 common reference to multiplexor 65 from conductor 40, through contacts 18CA, conductor 41 connector 79, cable conductor 47, connector 70, through relay contact 90AC, to conductor 107. "Sensor survey probes" 12, SPP 78 becomes idle until state S3 is detected by circuit 38 and signaled to SPP 78 through conductor 52. "Sensor" survey probes 12 are thereby prepared as current receiver

15 To begin the survey event, PSC 116 operates to program injector PS 22 to the prescribed voltage during state S2 and adjusts PS 22 voltage to limit current through meter 23 during the survey event to the prescribed value.

At the beginning of state S3, CMC 117 operates to open power gate 24 which applies the output of injection PS 22 to electrode 50 of "A" survey probe 12, producing a
20 current flow from electrode 50 through the earth to "B" survey probe 12, producing potentials at the surface measured and digitized by "sensor" survey probes 12.

Circuits 38 at each survey probe 12 operate to detect the transition from state S2

to state S3, corresponding to T^3 , synchronizing the ADCs of all "sensor" survey probes

12. All "sensor" survey probes' SPP 78 operate to produce the prescribed number of ADC samples of the arithmetical difference between reference signal 44 and electrode 50 sensor signals, performs the prescribed filtering processes, and other prescribed data
5 processing of the sensed voltage potentials during state S3, and stores the results in RAM/FLASH memory 62.

CMC 117 operates to enter state S0 by closing power gate 24. Circuits 38 of each survey probe detect removal of injection voltage from cable conductor 45 and signal the change to state S0 to SPP 78s via conductor 52. All survey probes SPP 78 operate to de-
10 activate all relay actuators 89, 90, 91, and 92 and enter state S1.

Referring to FIGS. 1, 2, 4, diagnostic testing and calibration of the multiplexor 65 and ADC 66 can be initiated by the a Client Terminal Browser by the investigator if accuracy of the data is questioned or programmatically by Survey Controller program 77 upon occurrence of a particular event detectable by SCP 77. In other embodiments,
15 diagnostic testing can be initiated for any other reason. In one embodiment, SCP 77 issues a command SPP 69 to execute a certain calibration and functional test of the multiplexor 65 and ADC 66. In one embodiment, ADC 66 operates to apply a precision internally sourced test voltage internally through multiplexor 65, internal buffer amplifier, and to ADC 66. A measurement of the precision voltage is taken and
20 compared to the known, expected value. SPP 78 adjusts gain and offset values of the internal buffer amplifier to achieve the expected value. Survey Probe Program 78 calibrates ADC 66. The Survey Controller may operate to send a command to SPP 78 to

execute a measurement of, for instance, a 9 volt un-regulated voltage by commanding the multiplexor 65 to apply the voltage on conductor 57 to the ADC 66 and instruct ADC 66 to measure, digitize, and store the value in memory. If the voltage is found to be less than the stipulated value at the time specified, an abnormal event can be recorded and transmitted to the SCP 77, which places the measurement in an abnormal event file in RAM/Flash memory 29 for analysis by a remote operator. An authorized operator may access Survey Controller Program's 77's webpage and through the processes identified in Fig. 2, access the abnormal event File. Other diagnostic tests appropriate for the particular embodiment are similarly implemented.

Referring to FIGS. 3 and 4, electronic switching device, 71 is connected through relay contact 89CA operable to modulate the electrical current passing through the circuit comprising PS 22, Gate 24, conductor 88, current meter 23, connector 79, to cable conductor 45 through relay contact 89AC, to conductor 56, to input to switching device 71, output from switching device 71, through relay contacts 91CA, conductor 85 through relay contacts 92CA, to connector 74, to one electromechanical, magnetic, or electrical stimulus injectors to receive electrical stimulation from connector 74, in response to signals applied to conductor 63 by SPP 78.

For electrical stimulus injectors, such as used in the electrical resistivity method embodiment of the present invention, the stimulus is an electrical current passing from the current injection survey probe 12, metal stake 50, through the earth, to the receiver metal stake 50 of receive survey probe 12, through relay contacts 92AC, conductor 85, through relay contacts 91AB, through relay contacts 89FD, through connector 70, cable

conductor 46, through conductor 40, through relay contacts 18DF, to conductor 55, to injector PS 22 return.

For electromechanical, magnetic, radio frequency, or other electrical stimulus injector embodiments of the present invention, the stimulus apparatus receives power through PS22, power gate 24, conductor 88, CM 23, connector 79, conductor 45, connector 70, relay contacts 89AC, current sensor 71A, current modulator 71, relay contacts 91CA, conductor 113, relay contacts 92CA, connector 74 and 74A, with return path through relay contacts 89FD, connector 70, to cable conductor 46, through connector 79, through relay contacts 18DF, through conductor 55, and to PS 22 return.

Electrical, vibration, seismic, magnetic, and other sensors connect to signal conditioner 64, through differential connectors 75B and 75C, conductors 83 and 84, through signal conditioner 64, to multiplexor 65 adaptable to apply the difference signal to analog to digital converter 66. SPP 78 operates to perform digital signal processing and filtering of the digitized data operates to store said data into RAM/Flash Memory, accessible to survey controller Survey probe Manager (SPM) 29 on command. Microphone 85 connects through conductor 72 to multiplexor 65. Also referring to FIG.8, Microphone 85 is coupled to the survey probe housing 49 coupled to conductive stake 50, adapted to produce electrical signals corresponding to sensed vibrations conducted from the ground 76, through conductive stake 59. Said signals are applied to multiplexor 65 through conductor 72. SPP 78 is operative to apply said signals through multiplexor 65 to ADC 66 for digitizing and filtering, and storing the digitized signals in RAM/Flash memory 62 available for access by SCP 77.

Referring to FIGS. 3, 4 and 5, a linear survey measurement cable array 11a is assembled on site by connecting a first cable 11 from survey controller 1 to a first survey probe 12, a second cable 11, from the first survey probe to a second survey probe, and a next cable 11 from the second survey probe to a next survey probe, until all the survey probes have been connected as shown in array 19. Connection of a survey probe 12 onto the chain, operates to charge energy storage device C1 of said survey probe. Power from C1 is supplied to operate said survey probe electronics 12. SPP 78 operates to initialize all electronics to state S1 and to send a data message to SCP 77 to announce its addition to the cable array. Said data message contains the serial number assigned during manufacture. SCP 77 responds to said data message with a command message containing a new address field. SPP 78, receives said command message, extract said new address field and stores it in memory 62. SPP 77 will generally operate to send future command messages to said survey probe addressing it by the new address.

A second embodiment of the present invention operates to acquire the survey probe serial number and operates to address future commands to said survey probe addressing it by said serial number. SPM 115 operates to maintain survey probe serial numbers, together with the order in which said serial number is reported, in RAM/FLASH memory 62. Said reporting order is the ordinate location on the array cable.

Referring FIG. 4, Temp Sensor 67 is adapted to sense the internal temperature of embedded computer 51 and produce a signal corresponding to the temperature. Periodically or on command by SCP 77, SPP 78 operates to measure the temperature and

with an internally generated precise reference voltage, perform a calibration process and make compensations and adjustments to said components to assure accurate operation of the multiplexor, internal buffers, amplifiers, and other internal circuits during survey events. SPP 78 operates to measure +9vdc 57 voltage level of energy source C1 at
5 prescribed times and calculates the operating time remaining before SPP 78 places embedded system 51 in idle mode to reduce power consumption.

Referring to FIG.8, conductive stake 50 is inserted into the earth operating to make electrical contact with the earth and to mount spring steel stake connector 74. Spring steel stake connector 74 fastens to conductive stake 50 and operates to mount
10 survey probe 12 onto stake 50 and provide electrical contact between contact rings 131 and conductive stake 50. Survey probe 12 comprises housing 124, assembled printed circuit board 112, PVC end plate 125 operating to seal the PCB assembly 112 from ingress of water and other chemicals and vapors. Female connector tubes 134 penetrate
15 PVC end plate 125 and PVChousing 124 and are sealed at holes of ingress 127, 126, 128, and 129 of housing 124 and at corresponding holes through end plate 125. Connector tubes 134 are soldered to PCB 112 solder pads and solder rings 121 which operate to conduct signals and power to PCB 112. Contact pins 132 operate to make electrical
20 contact between contact rings 131 and Relay 92 contact A of FIG.4. Connector 70 comprises molded connector shell 133, spring loaded bayonet type connector pins 130 electrically attached to conductors of cable segment 11, and low density compressible filler 135. Connectors 70 operate to make electrical contact between conductors of cable 11 and corresponding female connector tubes 134 when joined to survey probe housing

124. Low density compressible filler 135 operates to protect connectors pins 130 when not mated to housing 124.

Claims:

1. A system for measuring a property of a surface, the system comprising:
 - a plurality of survey probes; and
 - a survey controller configured to program the same survey probes for seismic or electrical measurements of the surface.
2. A system for measuring a property of a surface, the system comprising:
 - a plurality of survey probes, each having a unique identifier; and
 - a survey controller configured to automatically poll the survey probes to obtain each identifier and determine a relative order the probes.
3. The system of claim 2, each survey probe configured to:
 - disconnect a downstream neighbor survey probe and enter an idle state;
 - report its unique identifier to the survey controller if in the idle state and in response to a polling command from the survey controller; and
 - change to a state other than the idle state after reporting its unique identifier.
4. The system of claim 2, the survey controller configured to assign and transmit a different, unique identifier to each survey probe.
5. The system of claim 2, the survey controller and survey probes configured to communicate wirelessly.
6. The system of claim 2, the survey controller and survey probes being connected by a first number of conductors, the survey probes being configured to perform a second number of simultaneous measurements of the surface, and the second number not being limited by the first number.

7. The system of claim 2, the survey controller being remotely accessible through a computer network for remote control of the survey controller and the survey probes.
8. The system of claim 2, the survey probes being connected to the survey controller through three conductors, two conductors supplying power and a third conductor acting as a communications bus.
9. A system for measuring a property of a surface, the system comprising:
a survey controller; and
a plurality of survey probes configured to:
(a) collect signals associated with the surface;
(b) digitize the signals to form digital data; and
(c) store the digital data for later transmission to the survey controller.
10. The system of claim 9, where the survey probes are configured for performing both electrical and seismic measurements, and the signals comprising seismic or electrical signals.
11. The system of claim 9, the signals associated with the surface comprising signals that are generated in response to the surface being stimulated.
12. The system of claim 9, the survey controller and survey probes configured to communicate wirelessly.
13. The system of claim 9, the survey controller sending data to individually program survey probes to generate a stimulus simultaneously or according to another programmed timing scheme.
14. The system of claim 13, the stimulus comprising injection of current.

15. The system of claim 9, the survey controller sending data to individually program survey probes to form digital data and store the digital data according to a programmed timing scheme.
16. The system of claim 9, the survey controller and survey probes being connected by a first number of conductors, the survey probes being configured to perform a second number of simultaneous measurements of the surface, and the second number not being limited by the first number.
17. The system of claim 9, the survey controller being remotely accessible through a computer network for remote control of the survey controller and the survey probes.
18. The system of claim 9, the survey probes being connected to the survey controller through three conductors, two conductors supplying power and a third conductor acting as a communications bus.
19. A system for measuring a property of a surface, the system comprising:
a survey controller; and
a plurality of survey probes configured to:
 (a) collect signals associated with the surface; and
 (b) sample and hold the signals for later transmission to the survey controller.
20. A system for measuring a property of a surface, the system comprising:
a survey controller; and
a plurality of individually-addressable survey probes;
where the survey controller is configured to:
 (a) transmit a first signal to individually program survey probes to conduct one or more steps for measuring the property of the surface; and

- (b) transmit a second signal to cause survey probes to conduct the one or more steps according to a timing sequence.

- 21. The system of claim 20, the survey controller and survey probes configured to communicate wirelessly.
- 22. The system of claim 20, the survey controller further configured to transmit a third signal to diagnose survey probes.
- 23. The system of claim 20., the survey controller and survey probes being connected by a first number of conductors, the survey probes being configured to perform a second number of simultaneous measurements of the ground, and the second number not being limited by the first number.
- 24. The system of claim 20, the survey controller being remotely accessible through a computer network for remote control of the survey controller and the survey probes.
- 25. The system of claim 20, the survey probes being connected to the survey controller through three conductors, two conductors supplying power and a third conductor acting as a communications bus.
- 26. A system for measuring a property of a surface, the system comprising:
 - a survey controller; and
 - a plurality of individually-addressable survey probes;
 - where the survey controller is configured to transmit a diagnostic signal to individual survey probes to diagnose the individual survey probes.

27. A system for measuring a property of a surface, the system comprising:
a survey controller; and
a plurality of survey probes whose position relative to one another is automatically determined.
28. The system of claim 27, further comprising a transmitting beacon and where the position is determined using a signal from the transmitting beacon.
29. The system of claim 27, further comprising a radio frequency identification (RFID) system coupled to the probes and a Global Positioning System (GPS), the position being determined by combining identification information from the RFID system with positional location from the GPS.
30. The system of claim 27, the survey probes being in motion.
31. A system for measuring a property of a surface, the system comprising:
a plurality of survey probes; and
a survey controller configured to supply power to the survey probes using a power conduit;
where the survey probes automatically electrically disconnect from the power conduit while measuring the property and operate using an internal source of power when disconnected to reduce noise.
32. A system for measuring a property of a surface, the system comprising:
a plurality of survey probes; and
a survey controller that is remotely accessible through a computer network for remote control of the survey probes, the remote control comprising:
(a) remote initiation of a measurement of the property of the surface; and

- (b) remote collection of data from a measurement of the property of the surface.

33. The system of claim 32, the remote control further comprising remote processing of data from a measurement of the property of the surface.

34. The system of claim 32, the remote control further comprising remote diagnostic testing of survey probes.

35. The system of claim 32, the computer network comprising a wireless network.

36. A system for measuring a property of a surface, the system comprising:
a plurality of survey probes; and
a survey controller configured to program the plurality of survey probes to simultaneously apply a stimulus to the surface in an arbitrary pattern.

37. The system of claim 36, the pattern comprising a line pattern.

38. The system of claim 36, the pattern comprising a moving wave pattern.

39. A method for measuring a property of a surface, the method comprising:
collecting signals associated with the surface using a plurality of survey probes;
digitizing the signals using the plurality of survey probes to form digital data; and
storing the digital data using the plurality of survey probes for later transmission to a survey controller.

40. The method of claim 39, the method further comprising:
polling the survey probes using the survey controller to automatically:
(a) obtain an identifier of each survey probe; and
(b) determine a relative order of the survey probes.

41. The method of claim 39, where the survey controller and survey probes are connected by a first number of conductors, and the method further comprising performing a second number of simultaneous measurements with the survey probes, the second number not being limited by the first number.
42. The method of claim 39, the method further comprising:
controlling data acquisition, data processing, or data collection associated with the survey controller remotely over a computer network.
43. The method of claim 39, the survey probes being connected to the survey controller by one or more conductors that supply power, and the method further comprising automatically disconnecting the survey probes from the one or more conductors while measuring the property and operating using an internal source of power when disconnected to reduce noise.
44. The method of claim 39, the method further comprising automatically determining the relative position of the survey probes.
45. The method of claim 44, where the relative position is determined using (a) a transmitting beacon or (b) a radio frequency identification (RFID) system and a Global Positioning System (GPS).
46. The method of claim 39, the method further comprising performing a seismic and electrical measurement of the surface using the same survey probes.

ABSTRACT

Techniques for surface exploration and monitoring are presented. In representative embodiments, a system is provided that can perform multiple types of measurements of a surface. For example a single system of survey probes and one or more survey controllers can be used to offer both seismic and electrical measurements. A survey controller can be configured to automatically poll survey probes to obtain identifiers of the probes and determine a relative order the probes. Survey probes can be configured to: (a) collect signals associated with a surface; (b) digitize the signals to form digital data; and (c) store the digital data for later transmission to the survey controller. Relative positions of survey probes can be automatically determined using a transmitting beacon or other techniques. Survey probes can automatically disconnect from a power conduit while measuring a surface property and operate using an internal source of power when disconnected, to reduce noise. The survey controller can be remotely accessible through a computer network for remote control of the survey probes.

Charles Fort,

Further to my eMail communication of 13-August, we have now prepared and transmitted formal correspondence to you by Certified Mail. As a courtesy, I attach a copy of that correspondence. Please review the correspondence and respond as requested therein.

Thank you,
David

RE: U.S. Patent Application entitled: "TECHNIQUES FOR SURFACE
EXPLORATION AND MONITORING"
Application No: 10/827,104
Our Reference: 121-0003

Dear Charles:

This formal written correspondence follows my prior electronic correspondence of 16 June 2009, 30 June 2009, 5 July 2009, 27 July 2009 and 13 August 2009 (to you at rockforts@austin.rr.com and to your son Justin at justin4u@msn.com). Thank you for your response of 5 July 2009. Unfortunately, my subsequent correspondence remains unanswered. Accordingly, this formal written communication is being transmitted to you by certified mail to your postal address above.

ALLOWED CLAIMS

As you know, the above-identified pending US patent application names you and Justin Fort as inventors. On or about February 14, 2008, as part of a settlement of then ongoing litigation, both you and Justin assigned all right, title and interest in and to the above-identified application to your former employer, Advanced Geosciences, Inc. (AGI). Since then, my firm has, consistent with its representation of AGI, prosecuted the application to the point that the U.S. Patent Office (USPTO) has now identified certain claims that are allowable, i.e., which may mature into a granted US patent upon completion of certain formalities.

ADDITIONAL INVENTORS TO BE ADDED

In the course of our prosecution of the application, we have substantially amended the claims and it is these amended claims that the USPTO has indicated to be allowable. Based on our review, it appears that, at least with respect to the specific subject matter of claims as now amended, additional inventors contributed to the conception of the invention(s). Those additional inventors are: Mats Lagmanson, Liz Lagmanson, Markus Lagmanson and Bo Berglund.

Accordingly, consistent with USPTO regulations, we will petition to correct inventorship.

Charles P. Fort

RE: 121-0003
Page 2 of 2

PREVIOUSLY NAMED INVENTORS

Because we have not been able to consult with you, I have been unable to ascertain whether, given the specific subject matter of claims as *now amended*, either you or Justin should continue to be named as inventors, or deleted. Depending on the nature of any contribution that you or Justin made to the claims as *now amended*, either answer may be correct. I remain available to discuss, should you be willing to do so.

Nonetheless, the time has come for us to proceed to grant. Accordingly, out of an abundance of caution, we have prepared appropriate formal papers consistent with the proposition that you and Justin have contributed in at least some inventive way to the claims as *now amended*.

For avoidance of doubt, I have included a copy of the application as filed, together with a copy of the claims as now amended. Please advise me immediately if you believe that, relative to the subject matter of the claims as now amended, either you or Justin should no longer be named as an inventor.

WHAT I NEED FROM YOU IS ...

Subject to the foregoing, and based on the assumption that both you and Justin should be named as inventors, attached is a Declaration for your signature. Please review, sign where indicated and return the executed copy to me in the stamped return envelope provided. I would appreciate your prompt reply.

Thank you for your attention. If you have any questions, please do not hesitate to contact me at the above-listed number.

Very truly yours,

David W. O'Brien
